INDEX

AALDERS, L E, and I V Hall . New Evidence on the Cytotaxonomy of *Vaccinium* Species as revealed by Stomatal Measurements from Herbarium Specimens, 694
Aarkrog, A., and H C Rosenbaum : *Removal of Radiostrontium from* Milk, 767
Ababei, L., et *al.* : Influence of Ionizing Radiation on Glutaminase Activity in Mouse Brain and Liver, 1223
Abdullaev, Prof Kh M., *obituary*, 1152
Ability of a *Vibrio* grown on Benzoate to oxidize *para*-Fluorobenzoate (D. A Ali, A G. Callely and M. Hayes), 194
Ability of Some Antirheumatic Drugs to uncouple Oxidative Phosphorylation (M. W Whitehouse and J. M. Haslam), 1323
Ablations of Temperal Cortex . Relationship between Test Difficulty and the Visual Impairment in Monkeys with (G Ettlinger), 911
Abnormal Crystals in *Amoeba lescherae* (M Taylor), 291
Abreu, L. A., *et al.* · Mucoids of some Micro-organisms, 582
Abreu, R. R., et *al* · Mucoids of some Micro-organisms, 582
Absolute' Age . a Meaningless Term (Arthur Holmes), 1238
Absorption Correction in the Viscometry of Dilute Solutions of High *Polymers (H van Oene and* L. H Cragg), 1197
carus siro L , 1758, as a Species Complex : Flour Mite, (D. A. Griffiths), 908
cenaphthene Derivatives on Mitosis in *Pisum* Roots · Action of some (W. G. H Edwards), 688
0-Acetyl o-Nitrophenyl β-D-Galactoside (Y. Z. Frohwein), 775
cetylating Agents Quasi-Cholinergic Action of (W B. Geiger and J. Mandel), 1106
Acetylcholine · *Excitation and Inhibition of Brain-Stem Neurones by Noradrenaline* and (Dr. P B. Bradley and Dr J H. Wolstencroft), 840
Acetylcholine-evoked Salivary Secretion · Importance of Calcium for (W W. Douglas and A M Poisner), 379
Achar, B. N. N , and P Nilakantan : An Iterative Method for obtaining Statistical Frequency Distributions, 1237
Achimastos, A. S., and A N. Granitsas : Electrophoretic Mobility of Serum Post-heparin Tributyrinesterase, 69
  Heparin and Blood Lipids in Fasted Individuals, 173
Achutamurthy, P N., *et al.* : Calcium Hydroxide in Sucrose Solution as a Reagent for the Preparation of Water-dispersible Calcium Proteinates, 1313
Acid-Base Equilibria in Dilute Aqueous Alcohols containing Mineral Acids (C. F. Wells), 770
Acid Excretion and Serum Electrophoretic Patterns in the Normal and Bloated Bovine . Urinary 3-Methoxy-4-Hydroxymandelic (I. A. Dyer et *al*), 392
Acid Igneous Rocks · Formation of Gibbsite as a Primary Weathering Product of (J. P Watson), 1123
Acid-soluble Human Skin Collagen with Age : Quantitative Extraction of (S Bakerman), 375
Ackers, G K., and R L. Steere : Restricted-Diffusion Chromatography through Calibrated Columns of Granulated Agar Gel ; a Simple Method for Particle size Determination, 475
Acrolein (Edited by Dr. Curtis W. Smith), *review* by Dr. W. Forbes, 871
crylamide in the Presence of an Electric Field . Radiation-induced Solid-State Polymerization of Acrylonitrile and (A. Charlesby et *al.*), 574
rylonitrile and Acrylamide in the Presence of an Electric Field : Radiation-induced Solid-State Polymerization of (A. Charlesby et *al*), 574
tinomycins and their Derivatives · Structure-activity Correlations of (E. Reich et *al*), 743
tion of Iodine on Strained Keratin (J L. Hoare, O. Ripa and J B Speak*man*), 268
Action of Saponin on Biological Cell Membranes (A. D Bangham and R. W. Horne), 952 ; (A M. Glauert, J. T Dingle and J. A. Lucy), 953
Action of some Acenaphthene Derivatives on Mitosis In *Pisum* Roots (W. G. H Edwards), 688
Action of the Rete Mirabile in the Secretion of Gases by Blood-acidification in the Swim-bladder of the Eel (J B. Steen), 906
Activities of Various Concentrations of Triamcinolone Acetonide (W. W. Heseltine, J. M McGilchrist and R Gartside), 486
Adachi, T., et *al.* : Growth-promoting Effect of the B.S Factor and its Related Compounds, 673
Adaptive Teaching Machines, 1276
Addition of Alcohols to a Schiff Base co-ordinated to Copper (II), (C. M. Harris and E D McKenzie), 670
Adenosine Triphosphatase : Lipoprotein Nature *of Red Cell* (H. J. Schatzmann), 677
Adenosine Triphosphate and Phosphorylcreatine as Energy Supplies for Single Contractions of Working Muscle : Chemistry of Muscle Contraction (Dr D F Cain et *al*), 214
Adenosine Triphosphate Hydrolysis in Erythrocyte Ghosts : Directional Effects of Alkali Metal Ions on (Dr. R. Whittam), 134
Adenosine Triphosphate-induced Contraction of *Swollen* Mitochondria : Effects of Atractyloside and Oligomycin on Magnesium-stimulated *Adenosine Triphosphatase* and on (A Bruni and S. Luciani), 578
Adenotriphosphatase Activity of Stromata : Mechanism of X-ray Inhibition of the Sodium Pump in Human Erythrocytes (F. Bresciani et *al.*), 186
Adenovirus of Human Origin · Fatal Infection of Newborn Hamsters by an (H G. Pereira et *al.*), 244
Adipose Tissue Lipoprotein Lipase Activity In Rats of Two Different Ages (C Chlouverakis), 1103
Adler, N., et *al.* : Gibberellin-like Activity of Kudzu Vine Extract, 492
Adrenal Insufficiency . Potassium Excretion during (T. Fukuda and T. Koyama), 998
Adrenalectomy on 'Compensatory Hyperplasia of the Kidney : Effect of Starvation and of (G. E G. Williams), 1221
Adrenaline during its Physiological effect on *Intestinal Smooth Muscle* : Lack of Activation of Phosphorylase by (Prof E Bueding et *al.*), 944
Adrenocortical Inhibitor (SU-4885) on the Stress-Response of the White Blood Cells in the Teleost Fish, *Mollienesia latipinna* Le Sueur : Influence of Hypophysectomy and of an (John N. Ball and Anna M. Slicher), 1331
Adsorption of Human and Bovine Thrombin (F. Nour-Eldin), 782
Adult Education in Great Britain : History of (Dr. Thomas Kelly), *review* by W. E. Styler, 707
Advanced Inorganic Chemistry . A Comprehensive Text. (Prof. F. A. Cotton and Prof G. Wilkinson), *review* by Dr. R H. Prince, 855
Advances in Agronomy Vol. 13, (edited by A. G. Norman), *review* by H. V. Garner, 6
Advances in Clinical Chemistry (edited by Harry Sobotka and C. P. Stewart), Vol. 4, *review* by Prof. J. N Davidson, 1133
Advances in Cryogenic Engineering, Vol 7 : Proceedings of the 1961 Cryogenic Engineering Conference, *University of Michigan, 1961* (edited by K. D. Timmerhaus), *review* by Prof G G Haselden, 867
Advances in Electronics and Electron Physics, Vol. 15 (edited by L Marton assisted by Claire Marton), *review* by Dr. J. R Tillman, 845
Advances in Spectroscopy (edited by Dr. H. W. Thompson), Vol. 2, *review* by Dr. A Knowles, 1133
Advances in X-ray Analysis. Proceedings of the Sixth, Seventh, Eighth and Ninth Annual Conferences on Applications of X-ray Analyses. Vols. 1–4, *review* by Dr. J. H. Robertson, 706
Advantages of Iodine-125 for Studying Thyroid Function in Experimental Animals (Prof P. M. Daniel, Muriel M. Gale and Dr O. E. Pratt), 1065
Aedes *aegypti* (L) : Effect of Low Temperatures on Development, Hatching and Survival of the Eggs of (A. Weissman-Strum and S. H. Kindler), 1231
Aerosol Conference : The Prague (C N. Davies), 1272
Aerosol Particles : Thermophoresis of (B. V. Derjaguin and S. P. Bakanov), 669
Aerospace Medicine ((edited by Harry G Armstrong), *review* by J. Ernsting, 841
Aerospace Technology · Proceedings of the 6th Symposium on Ballistic Missile and, Los Angeles, 1961. Vols. 1–3 (edited by C. T. Morrow, L D. Ely and M. R Smith), *review* by D. G. King-Hele, 506
Agar Gel : Restricted-Diffusion Chromatography through Calibrated Columns of Granulated Agar Gel ; a Simple Method for Particle size Determination (R. L Steere and G K. Ackers), 475
Agar-*Gel Diffusion . Identification of the Origin of Animal Protein by* (D. Hay), 995
Age : ('Absolute') a Meaningless Term (Arthur Holmes), 1238
Agents inhibiting the Immune Response and the Growth of Tumours : A Screen for (M C Berenbaum), 384
Agrawala, V. K., and T. V Ramakrishnan : Neutron-Proton Interaction, 761
Agria affinis, (Fall.) : Pyridoxine Requirements of (J. S. Barlow), 193
Agricultural Research Station. Low Temperature Research Station, Cambridge Annual Report, 1961, 1167
Agriculture : An *Introduction to Statistical Science in (Dr. D. J. Finney)*, second edition, *review* by Dr J. A. Nelder, 6
Agronomic Studies : Commencement of the Institute of the International Centre for Advanced Mediterranean Agronomic Studies, 218
Agronomy : Advances in (edited by A. G. Norman), Vol 13, *review* by H. V. Garner, 6
Aguirre, M. J. R., and J. R. Villanueva : Production of Protoplast-like Structures from Various Species of Fungi, 693
Ahmed, K., et *al.* : Phosphoproteins and Sodium Transport, 484
Aida, Kō, and J. W. Foster : *Incorporation of Molecular Oxygen into Trans*-L-Epoxysuccinic Acid by *Aspergillus fumigatus*, 672
Air . Thermal and Photolytic Decomposition of the Lead Azides in (Dr. G. Todd and E. Parry), 250
Air Force Office of Scientific Research and the Society of Automotive Engineers, Inc. : Proceedings of the Third AFOSR Astronautic Symposium, Vol. 3, Vistas in Astronautics—1960, *review* by D. G. King-Hele, 841
Airglow : Observation of the (O,O) Band of the (${}^1\Delta g-{}^3\Sigma g^-$) System of Oxy*gen in the* Day and Twilight (J. F Noxon and A. Vallance Jones), 157
Air Movements in Clear Air and in Clouds : Radioisotope Technique for Tracing (R. A. Fookes et *al.*), 328

INDEX

Aisenstein, Simeon M : *Obituary* by Dr. R. L Smith-Rose, 414
Akroyd, T. N W. Concrete . Properties and Manufacture, *review* by A. J Newman, 1129
Aksenova, N N , et *al* : Influence of Ribonucleic Acids from the Liver on Implantation and Growth of Transplantable Tumours, 443
Alais, C , and P Jollès : Human Casein and its Caseinoglycopeptide, 1098
Alanine Dehydrogenase determined by one Gene in *Neurosopoa crassa* . Glutamic and (R R Burk and Dr. J A. Pateman), 450
Albino Hamster : Eliminative Response in the (Prof. E. Tobach and P Gold), 352
Albumin : Differences between Urinary Albumin and Serum (E. Merler et *al*.), 1207
Alcohol : Effect of Electric and Magnetic Fields on the Boiling Point of (R A. Anderson and S. Sardo Infirri), 267, *erratum*, 622
Alcohols to a Schiff Base co-ordinated to Copper (II) : Addition of (C M. Harris and E D. McKenzie), 670
Aldehydes : Oxidation of Vitamin A_1 and Vitamin A_2 Aldehydes to the Corresponding Acids by Enzymes from Pig and Rat Livers (M. S. Bamji et *al*.), 672
Alexander, E., et *al*. : Crimp in Cotton, 153
Alexander, Dr. P., et *al*. Progress of Cancer Research, 715
Alexander, Dr. P , and C. J. Dean : Sensitization of Radio-resistant Bacteria to X-rays by Iodoacetamide, 1324
Alga : Apparent Genetic Recombination in a Blue-Green (H D Kumar), 1121
Alginic Acid in Marine Brown Algae : Configuration of (Dr Eva Frei and Prof R. D Preston), 130
Ali, D. A., et *al*. : Ability of a *Vibrio* grown on Benzoate to oxidize *para*-Fluorobenzoate, 194
Ali, Prof M. A., and Dr. I. Hanyu : Intra-sub-specific Variation in Retinal Structure in *Sebastes marinus mentella*, 554
Aliphatic Guanidines : Ultra-violet Absorption Spectra of Simple (I Szilágyi et *al*.), 376
Alkali Halides . X-ray Line Broadening the (D. Lewis and H Pearson), 162
Alkaline Cations into Cat Spinal Motoneurones . Injection of (T. Araki et *al*.), 1319
Alkaline Phosphatase Variants in a Heteroploid Strain of Human Cells in Tissue Culture : Distribution of (J. J. Maio and L. L de Carli), 600
All-Sky Photometer : An (P V Kulkarni), 363
Allchin, Dr. F. R : Archaeology of Easter Island (Reports of the Norwegian Archæological Expedition to Easter Island and the East Pacific, Vol. 1), *review* 864
Allen, Leland C. : Method for Unravelling Complex Spectra, 663
Allibone, T. B : Closure of the *Merlin* Research Reactor, 1036
Allison, A C., et *al* : Fatal infection of New-born Hamsters by an Adenovirus of Human Origin, 244
Allium : Taxonomic Disposition of (D B. O Saville), 792
Allomyces Differential Synthesis of Nucleic Acids in Sexual Differentiation of (G. Turian), 493
Alouf, J. E., and M. Raynaud : Purification of Streptolysin O, 374
Alpher, R. A. : Laboratory Test of the Finlay-Freundlich Red Shift Hypothesis, 367
Alterations in the Carotenogenesis in *Staphylococcus aureus* after Adaptation to Pyrithiamine (S. K. Das and G. C. Chatterjee), 295
Alternatives in Testing Recognition Memory (H. C. A. Dale and A. D Baddeley), 93
Altman, K. I , et *al* : Biosynthesis of Creatine by the Kidney, 286
Altman, K. I , and S. S. Kurohara : Effect of Exposure to Ionizing Radiation on Creatine Concentration in Human and Rat Erythrocytes, 285
Aluminium Nitride in a Mild Steel (T N. Baker), 566
Aluminium and Manganese Toxicities in Plants related to Variety and Cation-Exchange Capacity : Resistance to (P. B Vose and P. J. Randall), 85
Amateur Radio Astronomy (Dr. R. D. Davies), 727
Amaurotic Idiocy . Chemistry of a Case of Juvenile (S A Barker et *al*), 64
Ambient Xenon : A Key to the History of Meteorites (Robert A Fish and Gordon G. Goles), 27
Ambrose, E. J , et *al*. : Electrophoretic Investigations of a Clone of Hamster Fibroblasts and Polyoma-transformed Cells from the same Population, 1068
American Geophysical Union : Second Western National Meeting, 220
American Institute of Biological Sciences : International Horizons in the Life Sciences (Prof G. Ledyard Stebbins), substance of an address delivered under the auspices of the, 611
American Mathematical Society Sixty-ninth annual meeting, 724
American Midwest Endemic-Exotic Earthworm Competition in the (J H. Stebbings), 905
American Society for Metals . Election of Officers, 815
American Society of Mechanical Engineers : Symposium on "High Pressure Measurement", 114
Amine-Alcohol Systems Hydrogen Bonding in Gaseous Mixtures (D. J. Millen and J. Zabicky), 889
Amino-Acid Esters of Phosphatidyl-Glycerol : Characterization of Lipo-amino-Acids as (Dr. Marjorie G Macfarlane), 136
Amino-Acid Incorporation into Protein by Liver Nuclear RNA : *In vitro* Stimulation of (Dr S. H. Barondes et *al*), 145
Amino-Acids in Nervous Tissue : Transamination of Aromatic (R. Haavaldsen), 577
γ-Amino Butyric Acid in Skin Lesions of Leprosy : Glutamic Acid Decarboxylase Activity of *Mycobacterium leprae* and Occurrence of (K. Prabhakaran and B. M. Braganca), 589
ε-Amino-caproic Acid : Inhibition of Spontaneous Splitting of γ-Globulin Preparations with (F. Škvařil and D Grunberger), 481
Amino-Compounds in Blood Platelets : Free (F. Nour-Eldin), 1219
Aminopterin as an Inducing Agent in Bacteriocinogenic Bacteria (R. Ben-Gurion), 1121
Ammonium Chloride labelled with Nitrogen-15 in Chick Embryos treated with β-Aminopropionitrile Inhibited Incorporation of (Annikki Salmi and E Kulonen), 895
Amoeba lescherae Abnormal Crystals in (M. Taylor), 291
Amoeba proteus studied with Labelled Specific Antibody : Dynamics of the Membrane of (Dr. L. Wolpert and C H. O'Neill), 1261
Amœbæ Preliminary Studies on the Basis of Cytoplasmic Inheritance in (Shirley E. Hawkins et *al*.), 396
Amore, G , et *al* : Lactate Dehydrogenase Isozymes in the Developing Rat Brain, 576
Amphiphilicity : Bimolecular Substitution in Octahedral Transition Metal Ions, and the Concept of (B. Bosnich), 1196
Amphotericin B and Gentian Violet and on the Anti staphylococcal Activity of Neomycin : Effect of Various Bile Salts on the Anticandidal Activity of (S. S. Schneierson, et *al*), 909
Amsterdam, D , et *al*. Effect of Various Bile Salts on the Anticandidal Activity of Amphotericin B and Gentian Violet and on the Anti staphylococcal Activity of Neomycin, 909
An Agar-Gel Diffusion Technique for demonstrating Antibody Productio by L ymph Node Cells in Tissue Culture (Richard H Egdahl, H Cress and J A Mannick), 183
An All-Sky Photometer (P V. Kulkarni), 363
An Apparent 20 Map-Unit Position Effect (Dr J B Gibson and Prof J. M Thoday), 661
An Application of Paper Electrophoresis to the Examination of Completeness of Reaction and Purification in the Synthesis of Radioactive Compounds (Richard W. Meikle), 61
An Early Test for Possible Skin Carcinogens in the Mouse Effect of Different Doses of 3-Methylcholanthrene in Benzene Solution (O H Iversen), 181
An Examination of HeLa Cancer Cells for Production of Gamma-Globulin (A. Z Budzyński, E. Broda, G. Kellner and J S. Frimmel), 892
An Experimental Evaluation of the Association of Pregnancy and Acute Leukæmia (Dr George H Gass and Robert T. Jarrett), 139
An Illustrated Catalogue of the Rothschild Collection of Fleas (Siphonaptera) in the British Museum (Natural History) (G H E. Hopkins and Miriam Rothschild), Vol. 3, *review* by Col Robert Traub, 304
An Increase in Sensitivity for the Assay of Penicillin in Milk (H M. Mei and L F L Clegg), 691
An Introduction to Statistical Science in Agriculture (Dr. D J. Finney), second edition, *review* by Dr. J A. Nelder, 6
An Iterative Method for obtaining Statistical Frequency Distributions (H. S. Heaps), 1236 , (P. Nilakantan and B N N. Achar), 1237
An X-ray Investigation of Lysozyme Chloride Crystals containing Complex Ions of Niobium and Tantalum , Three-dimensional Fourier Plot obtained from Data Extending to a Minimum Spacing of 5 Å (R. H. Stanford, jun., R. E Marsh and R. B. Corey), 1176
Anabolic, Uterotrophic Compound from Corn infected with *Gibberella zeae* : Isolation of an (Martin Stob et *al*), 1318
Anæsthesia and Analgesia (*The Practitioner*, 189, No 1130 ; 1962), 417
Anæsthetized Individuals Capillary Blood Standard Bicarbonate Values of Conscious and (R. L Searcy et *al*.), 70
Analyses of Ancient Glasses, 1790-1957 . A Comprehensive and Critical Survey (Prof. Earle R. Caley), Vol 1, *review* by Prof. R. W. Douglas, 1022
Analysis of Fatty Acids of Continuously Cultured Mammalian Cells by Gas-Liquid Chromatography (John J. Boyle and Ernest H Ludwig), 893
Analytical Chemistry : Comprehensive (edited by Prof Cecil L. Wilson and David W. Wilson), Vol 1C, *review* by A D. Wilson, 920
  Treatise on (edited by I M. Kolthoff and Philip J Elving), Part 2, Vol. 2, and Vol. 9, *review* by Dr. D. T Lewis, 854
"Analytical Chemistry and Applied Spectroscopy" : Fourteenth Pittsburgh Conference on, 1157
Anaphylaxis : Histochemical Demonstration of Nonspecific Esterase in Mast Cells of the Albino Rat with Properties Similar to Mast Cell Enzyme activated in (R. Keller), 281
Anaphylaxis in Mice with Fragments of Rabbit Antibody (L S Kind and J. W. Goodman), 79
Anatomy : Dr. R. L Cochrane appointed to a Research Fellowship in, 938
Anbar, M , and M. Inbar : Effect of Pyridoxal 5-Phosphate in the Presence of Vanadyl Ions on the de-iodination of Thyroxine, 1213
Andersen, Dr. P., and Sir John Eccles : Inhibitory Phasing of Neuronal Discharge, 645
Anderson, R. A., and S. Sardo Infirri : Effect of Electric and Magnetic Fields on the Boiling Point of Alcohol, 267, *erratum*, 622
Andrew, Prof E. R : Appointed to the chair of experimental physics and in 1964 Lancashire-Spencer professor of physics, 720
Andrews, F. N., et *al* . Isolation of an Anabolic, Uterotrophic Compound from Corn infected with *Gibberella zeae*, 1318
Andrews, J. R., and R J Berry : Modification of Radiation Effect on Mammalian Tumour Cells by Pharmacological Agents, 185
Andrews, Dr P. : Estimation of Molecular Weights of Proteins by Gel Filtration, 36
Δ^4-Androstenedione on the Reproductive Organs of Female Rats : Production of Cystic Changes in the Ovary Effect of Dehydroepiandrosterone and (Somnath Roy et *al*), 42
Angiotensin Activity : Unitage and Suggested Designation of (Dr Philip A Khairallah, et *al*), 1059
Angola (North-Eastern) : Pleistocene Climates and Cultures in (Dr. E M van Zinderen Bakker and Dr. J. D Clark), 639
Anhydride Copolymers as Viral Inhibitors Ethylene Maleic (E T. Feltz and Dr W Regelson), 642
Animal Behaviour, University of Cambridge : The Sub-Department of (Dr. W H. Thorpe), 1043
Animal Cell Suspensions . Isolation of Nuclei from (H. W. Fisher and H. Harris), 910
Animal Life (South African), Vol 8 (edited by Bertil Hanstrom, et *al*.), *review* by Prof. O. Lowenstein, 870
Animal Populations : The Exploitation of Natural (edited by E D. Le Cren and Dr M W Holdgate), The British Ecological Society, Symposium, No. 2, review by C. S. Elton, 3
Animal Protein by Agar-gel Diffusion : Identification of the Origin of (D. Hay), 995
Animal Tissues : Staining (Practical and Theoretical), (Edward Gurr), *review* by Dr. S. Bradbury, 1245
Animals Advantages of Iodine-125 for Studying Thyroid Function in Experimental (Prof P M Daniel et *al*.), 1065
  Citric Acid Tissues of Normal and Dystrophic (H H Taussky et *al*), 1100
  Experimental Production of Mesothelial Tumours of the Pleura by Implantation of Dusts in Laboratory (J. C. Wagner), 180
  Fiber Composition of Tough and Tender Muscles of Meat (Fergus Hill), 65
  Transfer of Substances between the Blood and Central Nervous System in Vertebrate and Invertebrate (J. E. Treherne), 1181
  Use of 'Seasonal' Regressions in Measuring Feed Intake of Grazing (L. J. Lambourne and T F Reardon), 961
Animals (Soil), (Prof. D Keith McE Kevan), *review* by Dr G. W. Heath, 870

nimals of Western Szechuan (Hung-Shou Pen), 14
Anisotropic Ionosphere : Induction to Electric Currents in a Uniform (A. A. Ashour and V C. A Ferraro), 260
Annals of the New York Academy of Sciences, Vol. 93, Article 10 : Radio Telescope Structure (Jacob Feld), *review* by R. F Tolson, 626
Annealing Behaviour of Phosphorus-32 Recoils in Potassium Chloride Crystals (J. S Butterworth and J G. Campbell), 982
Annison, E F, and R A Leng Possible Glucogenicity of Butyrate in Sheep, 674
Annual Change in the Declination ('Variation') in Western Scandinavia and the North Sea (Guro Gjellestad and Helge Dalseide), 55
Annual Review of Entomology, Vol. 7 (edited by Edward A Steinhaus and Ray F. Smith), *review* by H Oldroyd, 870
Annual Review of Nuclear Science, Vol 11 (edited by Emilio Segrè, in association with Gerhart Friedlander and Walter E. Meyerhof), *review* by Prof. E. B. Paul, 843
Annual Review of Plant Physiology, Vol. 12 (edited by Leonard Machlis, in association with Winslow R. Briggs), *review* by Prof. W. Stiles, 861
Anomalous Extinction Effects in X-ray Reflexion by Crystals (G N. Ramachandran and R. Parthasarathy), 1306
Anomalous Paramagnetism and Binuclear Structure of some Copper (II) Complexes of 8-Hydroxyquinoline (C M Harris, E. Kokot and S L Lenzer), 471
Anopheles gambiae Complex (G Davidson), 907
Anopheles gambiae Giles : *A Case of Dominant Dieldrin Resistance in* (G. Davidson and J. Hamon), 1012
Ansell, Dr. G B, and Dr. T. Chojnacki : Incorporation of 1-O-Phosphoryl-2-Dimethylaminoethanol and Phosphorylcholine into the Phospholipids of Brain and Liver Dispersions, 545
Antagonistic Effect of Urea and 2-Chloroethanol *on the Resistance to High* Salt Concentration in Wheat Seedlings (T. Miyamoto), 491
Antarctic Lake : Lake Vanda An (Dr. A. T Wilson and Dr. H. W. Wellman), 1171
Anterior Pituitary after Prolonged Cultivation *in vitro* and Transplantation into Pituitary-deprived Female Rats : *Functional Activity of the* (P. N. Martinovitch et *al*), 89
Anthony, Dr. H. D. : The Development of Scientific Method (The Commonwealth and International Library of Science, Technology and Engineering. History of Science and Technology Division, Vol. I), *review*, 306
Antibiotics . Cross-dependence between Neamine and other Basic (W. T. Sokolski et *al.*), 776
Antibody Fragments as shown by Paired Label Studies : Chemical Differences *between* (O Roholt et *al*), 773
Antibody Production by Lymph Node Cells in Tissue Culture . An Agar-Gel Diffusion Technique for demonstrating (Richard H Egdahl et *al.*), 183
Anticandidal Activity of Amphotericin B and Gentian Violet and on the *Anti staphylococcal Activity of Neomycin Effect of Various Bile* Salts on the (S S Schneierson et *al*), 909
Anticoagulating System : Reflex Nature of the Physiological (Prof B A. Kudrjashov and T. M Kalishevska), 647
Antigen between Human Red Cell and Glomerulus . Common (A. S. Markowitz), 487
Antigens with Microsomal Membrane Fractions derived from Ehrlich Ascites Carcinoma Cells : Association of Cell Surface (D. F. H. Wallach and E B Hager), 1004
Antimicrobial Agents Annual, 1960 : Proceedings of the Conference on Antimicrobial Agents held *In Washington, D.C., 1960 (edited by* Peter Gray, Benjamin Tabenkin and S. G. Bradley), *review* by Dr John Farquharson, 919
Antirheumatic Drugs to uncouple Oxidative Phosphorylation . Ability of Some (M W. Whitehouse and J M. Haslam), 1323
Antirrhinum majus Pollen to Calcium . *Chemotropic Response of* (J. P. Mascarenhas and L. Machlis), 292
Antitumour Agents · Induction of Lysogenic Bacteria as a Method of detecting Potential (J. Lein et *al*), 783
Antitumour Properties of Phleomycin (W T Bradner and M H. Pindell), 682
Antoniades, Dr. Harry N. (edited by) : Hormones in Human Plasma . Nature and Transport, *review* by Prof A S Parkes, 505
Aortic Connective Tissue to Cartilage and Bone induced by the Intravenous Injection of Papain : Metaplasia of (T. T. Tsaltas), 1006
Apartheid in South African Learned Societies, 1241
Aphids : Neurosecretion and the Transport of Secretory Material from the Corpora Cardiaca in (Bruce Johnson), 1338
Aphids as *Vectors of Plant Viruses* · A Conspectus of (J S. Kennedy, M. F. Day and V F. Eastop), *review* by Bruce Johnson, 1246
Apocrine Sweat Glands of the Scrotum of the Ram (G M. H. Waites and J. K. Voglmayr), 965
Apparent Genetic Recombination in a Blue-Green Alga (H D. Kumar), 1121
Apparent Relation between Solar Activity and the 440-Mc/s Radar Distance of Venus (W. Priester, M. Roemer and Th Schmidt-Kaler), 464
Appearance of Exothermic Peak in the Differential Thermal Curves of Vermiculites (P. Sinha), 765
Appearance of Parenterally Administered *Proteins in Saliva* (A. H. *Schein* and F. Tung), 1092
Appearance of Streptomycin Resistance following the Uptake of Transforming Deoxyribonucleic Acid in *Pneumococcus* (Dr. Harriett Ephrussi-Taylor), 748
Apple Fruit . Malic Enzyme Activity in (D. R. Dilley), 388
Apple Peel · Separation of the Enzymes present in the Mitochondrial Fraction from (A. C. Hulme and L S. C. Wooltorton), 388
Apple with Gibberellic Acid . Inhibition of Fruit-Bud Formation in (C. G. Guttridge), 1008
Applegate, H. G. : Effect of Halogenated Benzoic Acids on *Elodea densa*, 1117
Aqueous Alcohols containing Mineral Acids : Acid-Base Equilibria in Dilute (C F. Wells), 770

Charlton, T M : Some Early Work on Energy Methods in Theory of Structures, 734
Chatterjea, J B , et *al* : Double Exponential Nature in Chromium-51 Red Blood Cell Survival Curves in Hæmoglobin E Thalassæmia and Relation with Reticulocytes, 76
Chatterjee, G. C., and S K Das : Alterations in the Carotenogenesis in *Staphylococcus aureus* after Adaptation to Pyrithiamine, 295
Chaudhri, M M., and R. M Chaudhri : Photoelectrons and their Back Diffusion in Self-quenching Geiger-Muller Counters, 664
Chaudhri, R. M., and M. M Chaudhri : Photoelectrons and their Back Diffusion in Self-quenching Geiger-Muller Counters, 664
Chaussidon, J., et *al*. : Catalytic Decomposition of Cobalt (III) Hexammine Cations on the Surface of Montmorillonite, 161
Chelates formed by Tin IV with Ethylenediamine Tetraacetic Acid (T. D. Smith), 1092
Chemical Analysis : The Working Tools, edited by C. R N Strouts, H. N. Wilson and R. T. Parry-Jones with the assistance of J H Gilfillan Vols. 1, 2 and 3, revised edition, *review* by Dr. D T. Lewis, 854
Chemical Difference between Normal Human Hæmoglobin and Hæmoglobin-I (M. Murayama), 276
Chemical Differences between Antibody Fragments as shown by Paired Label Studies (O. Roholt, A Shaw and D. Pressman), 773
Chemical Education British Committee on, Chairman appointed, 1039
Chemical Engineering Formation of a Research Committee (Institution of Chemical Engineering), 415
  Dr R. Long appointed reader in, 938
Chemical Heterogeneity of Hæmoglobin O (Dr C Baglioni and Dr. H Lehmann), 229
Chemical Process Plants . Economic Life of (H B. Milner), 1046
Chemical Society, et *al* . Report of a Symposium held on "Chemistry and Mental Disease" (Dr E H P. Young), 617
Chemical Stimulation of the Peripheral Trigeminal Nerve (William W. Dawson), 341
Chemie, Astronomie, Geophysik und Technik : Zahlenwerte und Funktionen aus Physik, (Landolt-Bornstein), Band II, Teil 4, *review* by S P Cooper, 868
Chemiluminescent . Secondary Processes in (R F Vassil'ev), 668
Chemistry Dr N M Atherton appointed lecturer in, 418
  Dr J N Murrell appointed honorary lecturer in, 418
  Dr. A E Pedler appointed lecturer in, 938
  Dr. Konràd Singer appointed to a readership in, 622
  J D Smith appointed lecturer in, 418
  Dr R A Wall appointed lecturer in, 622
  Dr M G H Wallbridge appointed lecturer in, 938
  Annual Studies in the History of (Chymia), Vol 7 (edited by Henry M Leicester), (Edgar F. Smith Memorial Collection University of Pennsylvania, University of Pennsylvania and Division of History of Chemistry, American Chemical Society), *review* by Prof J R. Partington, 854
  Effect of Instrument Development on the Progress of (Sir Harry Melville), 405
  Historical Studies in the Language of (Maurice P. Crosland), *review* by Prof John Read, 1021
  A History of, Vol. 3 (Prof. J. R. Partington), *review* by Prof. John Read, 853
Chemistry and Mental Disease (Dr E. H. P. Young), 617
Chemistry of a Case of Juvenile Amaurotic Idiocy (S A Barker, S. H. I. Bayyuk and M Stacey), 64
Chemistry of Muscle Contraction Adenosine Triphosphate and Phosphorylcreatine as Energy Supplies for Single Contractions of Working Muscle (Dr. D F. Cain, A A Infante and Prof. R. E Davies), 214
Chemists : Great (edited by Eduard Farber), *review* by Prof John Read, 1021
Chemo-sensitivity and its Relationship to Peripheral Nerve Carbon Dioxide-sensitivity Central Respiratory (I P Priban), 779
Chemotherapy Nicotinamide 6-Mercaptopurine Dinucleotide and Related Compounds Potential Sources of 6-Mercaptopurine Nucleotide in (Dr M. R Atkinson et *al*.), 35
Chemotherapy in Malaria Control, 425
Chemotropic Response of *Antirrhinum majus* Pollen to Calcium (J P. Mascarenhas and L Machlis), 292
Cherry, Colin, edited by . Information Theory . Papers read at a Symposium on Information Theory held at the Royal Institution, London, 1960, *review* by Prof. L. S Goddard, 205
Chester, Dr G V , and Dr. A Howie . Solid-State Physics, 119
Chick Chorio-Allantoic Membrane Effect of Skeletal Muscle Homogenates on the Differentiation of the (Robert Rich and Michael Filosa), 1329
Chick Embryos treated with β-Aminopropionitrile . Inhibited Incorporation of Ammonium Chloride labelled with Nitrogen-15 in (Annikki Salmi and E Kulonen), 895
Chickens : Cortisol Metabolizing Activity of Spleen and Liver of Erythroblastosis-afflicted and Normal Chickens *in vitro* (J. Tuzson and P. Kertai), 679
  Effect of Neonatal Thymectomy on the Immune Response in the (N. L Warner and A Szenberg), 784
  Relationship between Splenomegaly, Runting and Tolerance to Skin Homografts in (J B Solomon), 558
  Relative Contributions of the Thymus and the Bursa of Fabricius to the Maturation of the Lymphoreticular System and Immunological Potential in the (B W. Papermaster and Prof R. A Good), 838
Chicken Embryos during Incubation : Influence of Incandescent and Coloured Light on (J. V. Shutze *et al*), 594
Chidester, C. G , et *al* : Cross-dependence between Neamine and other Basic Antibiotics, 776
Chimæroid Fishes : Osmoregulation in (R. Fange and K. Fugelli), 689
China : Science and Civilisation in (Dr. Joseph Needham), Vol 4, Part 1, *review* by Dr E H. Hutten, 844
Chlorella pyrenoidosa : A Giant Form of (M R-Lopéz and R. R-Candela), 691
Chloride (Silver) . Polygonization in (M. T. Sprackling), 979
Chloride Ions during the Action Potential of *Nitella* . Efflux of (L J Mullins), 986
Chloroauric Acid Solution . γ-Ray-induced Formation of Gold Sol from (H. Fujita et *al*.), 666
2-Chloroethanol on the Resistance to High Salt Concentration in Wheat Seedlings : Antagonistic Effect of Urea and (T Miyamoto), 491
Chloronitrobenzene : Genetic Control of Tolerance to Tetra- and Penta-Chloronitrobenzene in *Hypomyces solani f. cucurbitae* (S G. Georgopoulos), 359
Chlorophyllide and the Formation of Lamellæ in Chloroplasts . Phytylation of (S Klein), 992
Chloroplasts Phytylation of Chlorophyllide and the Formation of Lamellæ in (S Klein), 992
Chlorosulphonic-Acid from 'Waste', Ba^{35}SO$_4$ Preparation of ^{35}S- (N Tudball), 580
Chlortetracycline on the Sporulating Cells of Bacilli and the Atypical Development of Spores : Binding of (Vladimír Vinter), 1336
Chlouverakis, C. : Adipose Tissue Lipoprotein Lipase Activity in Rats of Two Different Ages, 1103
Chmielewska, I., and Z Kasprzyk : Pyrethrin and Gallotannin in the Flowers of Peony, 776
Chojnacki, Dr T , and Dr. G B Ansell : Incorporation of 1-O-Phosphoryl-2-Dimethylaminoethanol and Phosphorylcholine into the Phospholipids of Brain and Liver Dispersions, 545
Cholesterol Oleate on the Phagocytic Function of the Reticulo-Endothelial System : Effect of (A E Stuart), 78
Chondrus crispus : A Comparison of Polysaccharides of *Hypnea musciformis* and (R D. Hamilton and J J Carroll), 1200
Chorioallantoic Fluid during the First Minutes of Virus Infection : Sialoresponsin : Neuraminic Acid-containing Substance(s) which Accumulates in (Prof. S. Bogoch et *al*.), 649
Chorio-Allantoic Membrane (Chick) Effect of Skeletal Muscle Homogenates on the Differentiation of the (Robert Rich and Michael Filosa), 1329
Chorion (Human) as a Membrane System : *In vitro* Investigations of the (Dr F C. Battaglia et *al*), 1061
Christensen, G. M., and Kathleen Simo : Quantitative Analysis of Sugars in Royal Jelly, 1208
Christmas Factor Inhibitor by Means of Boyden's Technique : Immunological Investigation of a (J Colombani and E. Terrier), 1111
Christophorou, L G , and J B Birks Resonance Interactions of Fluorescent Organic Molecules in Solution, 33
Chromatographic Isolation of Leucodrin (A W. Murray), 484
Chromatography A Tritium Isotope Effect on Ion Exchange (Hubert Gottschling and Prof E Freese), 829
Chromatography through Calibrated Columns of Granulated Agar Gel , a Simple Method for Particle-size Determination : Restricted-Diffusion (R. L. Steere and G K Ackers), 475
Chromatophoric Responses of Eyestalk-less Shrimps (C. Pasteur-Humbert), 790
Chromium-51 : Viability of Ehrlich Ascites Tumour Cells exposed to Sodium Chromate labelled with (P C Vincent), 179
Chromium-51 Red Blood Cell Survival Curves in Hæmoglobin E Thalassæmia and Relation with Reticulocytes Double Exponential Nature in (F. Hosain *et al*), 76
Chromizing : High-Frequency (I A Menzies and D Mortimer), 981
Chromobacterium violaceum Divergent Pathways of Indole Metabolism in (O K Sebek and H Jäger), 793
Chromophores in the Carbonyl-Amino System Development of (H S Burton, D. J. McWeeny and D O Biltcliffe), 40
Chromosomal Rearrangements and the Evolution of Haptoglobin Genes (O Smithies, G. E Connell and G. H Dixon), 232
Chromosome Breakage in *Vicia faba* by Monochloramine (Robert H Fetner), 1122
Chromosome Structure and Function : Implications in—A Molecular Model for Biological Contractility (Dr. Arthur Cole), 211
Chromosomes in the Mitotic Prophase of Ascites Tumour Cells : Fine Structure of (G. Yasuzumi and R Sugihara), 395
Chubb, J C , et *al* Occurrence of the Genus *Archigetes* in Britain, 494
Chymia : Annual Studies in the History of Chemistry, Vol. 7, edited by Henry M Leicester (Edgar F. Smith Memorial Collection University of Pennsylvania. University of Pennsylvania and Division of History of Chemistry, American Chemical Society), *review* by Prof. J R Partington, 854
Ciba Foundation Lectures (fourteenth annual) "The Future of Man Evolutionary Aspects", 322
Ciba Journal, Autumn 1962, No 23, 1041
Ciliary Beat measured with a Photo-sensitive Cell Frequency of (T. Dalhamn and R. Rylander), 592
Cirrhosis (Human) A Phagocytic and Protein-forming Mesenchymal Cell in (F. Schaffner and H Popper), 684
"Citrate Metabolism" Bone and Tooth Society Symposium, 418
Citric Acid in Tissues of Normal and Dystrophic Animals (H. H Tausky, A. Washington, E Zubillaga and A T Milhorat), 1100
Civil Engineering J. Graham appointed lecturer in, 417
  Dr B. P Hughes appointed lecturer in, 938
  P. J. Reilly appointed lecturer in, 938
Clapp, Jane : Museum Publications : A Classified List and Index of Books, Pamphlets and other Monographs, and of Serial Reprints, Part 2, *review* by F. S Wallis, 871

Effect of Adsorbed Proteins on the Wettability of Hydrophilic and Hydrophobic Solids (L. Vroman), 476
Effect of Anti-Tumour Agents on Non-Dividing Cells (Dr. M. C. Berenbaum and Marlene Calley), 656
Effect of Bone-Marrow on Regeneration of Liver of X-Irradiated Rats (E. Czeizel, G. Vaczó and Dr P. Kertai), 240
Effect of Bradykinin on Isolated Coronary Arteries (V Kovalčík), 174
Effect of Carbon Dioxide and Diphenylhydantoin on the Partition of Tri-iodothyronine labelled with Iodine-131 between the Red Cells and the Plasma Proteins (C Osorio, D J. Jackson, J. M. Gartside and A. W. G. Goolden), 275
Effect of Cholesterol Oleate on the Phagocytic Function of the Reticulo-Endothelial System (A. E. Stuart), 78
Effect of Cortisone on the Urinary Excretion of Histamine in the Hyperthyroid Rat (T. Bjuro, H Westling and H Wetterqvist), 1213
Effect of Dehydroepiandrosterone and Δ^4-Androstenedione on the Reproductive Organs of Female Rats : Production of Cystic Changes in the Ovary (Somnath Roy, Virendra B. Mahesh and Robert B Greenblatt), 42
Effect of Electric and Magnetic Fields on the Boiling Point of Alcohol (R. A. Anderson and S. Sardo Infirri, 267, *erratum*, 622
Effect of Exposure to Ionizing Radiation on Creatine Concentration in Human and Rat Erythrocytes (S. S. Kurohara and K I. Altman), 285
Effect of Feeding X-ray Irradiated Coliform Bacilli to Tumour-bearing Mice (Dr. A. Compton), (195, 1273), *erratum*, 220
Effect of Freezing of Soil on Denitrification (J. W. McGarity), 1342
Effect of Glucagon on Liver Glycolysis (R. Metz and J. M. Salter), 1094
Effect of Halogenated Benzoic Acids on *Elodea densa* (H. G. Applegate), 1117
Effect of Instrument Development on the Progress of Chemistry (Sir Harry Melville), 405
Effect of Large Variations in External Potassium on the Oxygen Consumption of Rat Heart Strips (W. J. Whalen and O. Weddle), 274
Effect of Low Temperatures on Development, Hatching and Survival of the Eggs of *Aedes aegypti* (L), (A. Weissman-Strum and S. H Kindler), 1231
Effect of Methylene Blue on Red Cell Glutathione (Linda Bockris and R Sephton Smith), 278
Effect of Moisture Movement of Natural Aggregate on Concrete (H. B. Milner), 943
Effect of Morphine on Rats bearing Walker Carcinosarcoma 256 (Harry Sobel and George Bonorris), 896
Effect of Mucus on the Swimming-Rate of Sperms (D. Tampion and R. A. Gibbons), 290
Effect of Multi-site Mutation to Colicine Resistance on Recombination and Segregation in *Escherichia coli* (J. P. Gratia), 1337
Effect of Neonatal Thymectomy on the Immune Response in the Chicken (N L. Warner and A. Szenberg), 784
Effect of Parasitism on Gram-positive Bacteria, with Reference to the Origin of Certain Types of Virus (Dr. Phyllis Pease and Dr. K. A. Bisset), 357
Effect of Phenylthiocarbamide on Viability of *Drosophila melanogaster* Strains with High and Low Tyrosinase Activity (H. W Lewis and H. S. Lewis), 192
Effect of Potassium Depletion on Lactic Dehydrogenase Activity in the Rat Nephron (Robert C. Muehrcke and Sjoerd L Bonting), 70
Effect of Pyridoxal 5-Phosphate in the Presence of Vanadyl Ions on the De-iodination of Thyroxine (M. Anbar and M. Inbar), 1213
Effect of Skeletal Muscle Homogenates on the Differentiation of the Chick Chorio-Allantoic Membrane (Robert Rich and Michael Filosa), 1329
Effect of Starvation and of Adrenalectomy on Compensatory Hyperplasia of the Kidney (G. E G. Williams), 1221
Effect of Thiouracil on the Development of Mammary Tumours in Rats induced with 9,10-Dimethyl-1,2-Benzanthracene (J E Helfenstein, S. Young and A R Currie), 1108
Effect of Thymidine Analogues on Reproductive Morphogenesis in *Arabidopsis thaliana* (L) Heynh (J A. M. Brown), 51
Effect of Tri-iodothyronine on Ethanol Metabolism in the Dog (F W. Kinard, M. G Hay and F W Kinard, jun.), 380
Effect of Ultra-high Vacuum on *Bacillus subtilis* var. *niger* (Frank A Morelli, Francis P. Fehlner and Charles H Stembridge), 106
Effect of Urea on the Synthesis of Polynucleotides with Crude Bacterial Extracts (F Cramer and K Randerath), 1209
Effect of Various Bile Salts on the Anticandidal Activity of Amphotericin B and Gentian Violet and on the Anti staphylococcal Activity of Neomycin (S. S. Schneierson, D. Amsterdam and E. Perlman), 909
Effects of Atractyloside and Oligomycin on Magnesium-stimulated Adenosine Triphosphatase and on Adenosine Triphosphate-induced Contraction of Swollen Mitochondria (A. Bruni and S Luciani), 578
Effects of Intravenous Phospholipid containing Phosphatidyl Serine on Blood Clotting with Particular reference to the Russell's Viper Venom Time (Dr J. F. Mustard, W. Medway, H G. Downie and H. C. Rowsell), 1063
Effects of Kinetin and Other Plant Growth Regulators on Starch Degradation (D. Boothby and S T C Wright), 389
Effects of Morphine on Uptake of Glucose and Synthesis of Glycogen in Muscle of Normal and Chronically Morphinized Rats (C. H. Lee Peng and E O'F Walsh), 171
Effects of Partial and Microbeam Irradiation of Cells (Dr. C. L Smith), 728
Effects of Stilboestrol and Thiouracil on the Electrocardiograms of the Sheep (Dr. D. N. Mullick and V. N Murty, 194, 1285), *erratum*, 724
Effects of Thiols on Oxytocin and Vasopressin Receptors (P J. Martin and H. O. Schild), 382
Effects of 'Visible' Light on 5-Bromouracil-labelled DNA (A. Wacker, H. D. Mennigmann and W. Szybalski), 685
Effect on the Plasma Citrate of Treatment of Primary Hypothyroidism with Triiodothyronine (R. D. Cohen), 486

Food Science : The Nuffield Foundation—Scholarships in, 20
  Training and Research in, 1
Food and Agriculture Organization of the United Nations : FAO Nutrition Meetings Report Series, No 31, *Evaluation of the Toxicity of a Number of Antimicrobials and Antioxidants*, Sixth Report of the Joint FAO/WHO Expert Committee on Food Additives, 726
  FFHC Basic Study No 5, *Nutrition and Working Efficiency*, 821
  FFHC Basic Study No 6, *Education and Training in Nutrition*, 821
  Forestry and Forest Products Studies, No. 14 (C W Scott), 1042
  Freedom from Hunger Campaign–Basic Study No 3, 723
  E Nyholm appointed as fisheries economist for Pakistan, 721
  Dr N A Osara appointed Director of the Forestry and Forest Products Division, 519
Fookes, R A , et *al* Radioisotope Technique for Tracing Air Movements in Clear Air and in Clouds, 328
Foot-and-Mouth Disease Vaccines for the Immunization of Cattle : Use of *BHK* 21 Cells in the Preparation of Mouse Attenuated Live (G N Mowat *et al*), 655
Foraminiferal Genera : Type Species of (F T Banner and W J Clarke), 1334
Forbes, S. T , and Prof. R V Jones · Sub-Acoustic Waves from Recent Nuclear Explosions, 1170
Forbes, Dr W Acrolein, *review*, 871
Forces in Colloidal Systems (Dr R. H Ottewill and Dr G D. Parfitt), 940
Ford, Dr C E , *et al* · Initiation of Immune Responses by Small Lymphocytes, 651
Ford Foundation Grant awarded to the University of Delhi, 1269
Foreign Language Barrier in Science and Technology (A Study based upon three investigations carried out in the Research Department by Moira Phillips), Aslib, 1044
Forensic Immunology, Medicine, Pathology and Toxicology Third International Meeting on, 220
Forest Products Research Laboratory (D S I.R) : Director appointed, 519
Forestry · Research Assistantships and Fellowships in, 322
Forestry and Forest Products Division of the Food and Agriculture Organisation Dr. N A. Osara appointed Director of the, 519
  Forestry and Forest Products Studies, No 14 (C W. Scott), 1042
Formation by Oxidizing Agents of Free Radicals in Wool and Silk (M. Burke, P. Kenny and C H Nicholls), 667
Formation of Gibbsite as a Primary Weathering Product of Acid Igneous Rocks (J. P. Watson), 1123
Formimino-glutamic Acid Urinary Excretion of Urocanic Acid and (M C. Bennett and I Chanarin), 271
Forrest, H S , and S Nawa Structure of Sepiapterin and Isosepiapterin, 372
  Synthesis of the Yellow Pteridine, Isosepiapterin, 169
Forrest, W. W., and D J Walker Thermodynamics of Biological Growth, 990
Forrester, J A , et *al* Electrophoretic Investigations of a Clone of Hamster Fibroblasts and Polyoma-transformed·Cells from the same Population, 1068
Fortune, Dr. R F · Politics of the Kula Ring An Analysis of the Findings of Bronislaw Malinowski, *review*, 865
Foss, Prof Martin : Logic and Existence, *review* by F I G. Rawlins, 1133
Fossil Hand Bones from Olduvai Gorge (Dr. John Napier), 409
Fossil Particle Tracks in Natural Micas Observation of (P B. Price and R M. Walker), 732
Foster, J. W , and Kō Aida . Incorporation of Molecular Oxygen into *Trans*-L-Epoxysuccinic Acid by *Aspergillus fumigatus*, 672
Foster, Dr. P. J. · Appointed lecturer in Fuel Technology and Chemical Engineering, 418
Fothergill, J E , et *al.* · Kidney Specific Antigen and its Species Distribution, 385 ; Uptake of Proteins by Malignant Cells, 1108
Foulkes, J., et *al.* : Species of *Tetrahymena* from the British Garden Slug *Milax budapestensis*, 1008
Fourier Plot obtained from Data extending to a Minimum Spacing of 5 Å : An X-ray Investigation of Lysozyme Chloride Crystals containing Complex Ions of Niobium and Tantalum : Three-dimensional (R. H. Stanford, jun. et *al*), 1176
Fowler, R. G. · Possible Hydrodynamical Character of Moving and Stationary Striations, 976
Fox, Prof. T. R. C. : *Obituary* by Sir John Baker, 811
Fractionation of Nitrogenous Compounds from Corn Leaves (The late James G Dickson and James L. Lords), 1099
Fractionation of Partially Isotactic Polypropylene Oxide (C Booth, M N. Jones and E Powell), 772
Fraga, E , et *al* Electrophoretic Pattern of the Soluble Proteins of a Pineal Body Extract, 274
Fragmentation of Meteor Bodies (Dr B Levin), 527
Franco, A P , et *al* Frequency of Atypical Pseudocholinesterase in British and Mediterranean Populations, 599
Frank-Tishel, Judith, and B Kessler Dehydration-induced Synthesis of Nucleic Acids and Changing of Composition of Ribonucleic Acid : A Possible Protective Reaction in Drought-Resistant Plants, 542
Frankland Society Substance of the Eighth Frankland Oration, delivered to the Lancastrian Society by Sir Christopher Ingold, "Education of a Scientist", 1030
Franklin Medal awarded, 220
Franzke, C J , and M E Sanders . Somatic Reduction of Tetraploid Sorghum to Diploid Mutants following Colchicine Treatment, 696
Fraser, Dr James Nature Adrift : The Story of Marine Plankton, *review* by J S Colman, 858
Frazier, A W , et *al.* . Octacalcium Phosphate and Hydroxyapatite, 1050
Free Amino-Compounds in Blood Platelets (F Nour-Eldin), 1219
Free Radical Reactions involving no Unpaired Electrons (M B. Neiman, E. G Rozantzev and Yu G Mamedova), 472
Free Radicals formed during the Oxidation and Reduction of Peroxides (W T Dixon and R O C Norman), 891
Freedom from Hunger Campaign—Basic Study, No 3 (Food and Agriculture Organization of the United Nations), 723
Freese, Prof E , and Hubert Gottschling A Tritium Isotope Effect on Ion Exchange Chromatography, 829
Freezing Metal Structures Diamond Replication of (E H Hull), 469
Freezing and Supercooling : Biological Effects of (Dr. Audrey U Smith), (Monographs of the Physiological Society, No 9), *review* by Dr. E C Bate-Smith, 859
Frei, Dr. Eva, and Prof R D Preston : Configuration of Alginic Acid in Marine Brown Algæ, 130
French Science News, No 1, January-March, 1962 (National Centre of Scientific Research, France), 222
  No. 2, April-June, 1962 (Nuclear Research in France), 420
Frequency Increase in Maximum Usable Frequency for Two-hop Transatlantic Propagation due to Horizontal Gradients (H P Williams), 256
Frequency of Atypical Pseudocholinesterase in British and Mediterranean Populations (Chr Kattamis, L Zannos-Mariolea, A. P. Franco, J. Liddell, H. Lehmann and D. Davies,), 599
Frequency of Ciliary Beat measured with a Photo-sensitive Cell (T. Dalhamn and R Rylander), 592
Fricker, D J , and D. J. C Jones . Iso-Butyric Acid in Silage, 1211
Friends of the Lake District . *Report and Newsletter*, July 1962, 1156
Frilled Shark · New Records for Distribution of the (A Wheeler), 689
Frimmel, J S , et *al.* : An Examination of HeLa Cancer Cells for Production of Gamma-Globulin, 892
Fripiat, J. J., et *al* · Catalytic Decomposition of Cobalt (III) Hexammine Cations on the Surface of Montmorillonite, 161
Frog Skeletal Muscle Variability of Twitch Potentiation in (Allen Isaacson), 381
Frohwein, Y Z 6-O-Acetyl o-Nitrophenyl β-D-Galactoside, 775
Frost Injury in Living Cells (Eizo Asahina), 445
Fruit . Inhibition of the Evolution of Ethylene and the Ripening of Fruit by Ethylene Oxide (M Lieberman and L. W Mapson), 660
Fruit-Bud Formation in Apple with Gibberellic Acid . Inhibition of (C G. Guttridge), 1008
Fuel Technology and Chemical Engineering : Dr P. J. Foster appointed lecturer in, 418
  J. Swithenbank appointed lecturer in, 418
Fugelli, K., and R Fange Osmoregulation in Chimæroid Fishes, 689
Fujita, A , et *al* Microscopic Examination of Highly Radioactive Fall-out Particles, 529
Fujita, H , et *al* γ-Ray-induced Formation of Gold Sol from Chloroauric Acid Solution, 666
Fukuda, T , and T Koyama : Potassium Excretion during Adrenal Insufficiency, 998
Fukuda, T , et *al* Synthetic Diet for Silkworm Raising, 53
Fulbright Travel Grants, 418
Functional Activity of the Anterior Pituitary after Prolonged Cultivation *in vitro* and Transplantation into Pituitary-deprived Female Rats (P N. Martinovitch, N. Zivkovitch and D Pavitch), 89
Fundamentals of Electrical Science (C. T. Baldwin), *review* by Prof A. H M. Arnold, 867
Fungal Culture Filtrate : Resolution of Endopolygalacturonase and a Macerating Factor in a (R. J W Byrde and A H. Fielding), 1227
Fungi Production of Protoplast-like Structures from Various Species of (M. J R Aguirre and J R Villanueva), 693
  Use of Camphor-induced Polyploidy to determine the Place of Meiosis in (E. Sansome and B J Harris), 291
Further Comments on Attempts by H Moissan, J B Hannay and Sir Charles Parsons to make Diamonds in the Laboratory (Prof Kathleen Lonsdale), 104
Further Isotopic Age Measurements on Rocks from North-eastern Greenland (J L Kulp, R. Kologrivov, J Haller and L. Koch), 160
Furunculosis in Salmon Kelts (Ann Hewetson), 1009
"Future of Man Evolutionary Aspects" Fourteenth Annual Ciba Foundation Lectures, 322
Future of Teaching Machines (Prof B F. Skinner), 1160

Fuzl, M , and I. Pillis : Production of Opacity in Egg-Yolk Medium by *Listeria monocytogenes*, 195

GAAFAR, A. K. : A New Method for grafting Sweet Potato, 903
Gabbutt, Peter D. 'Nests' of the Marine False-Scorpion, 87
Gabuzda, T C., *et al* : Comparative Metabolism of Hæmoglobins A and F in Thalassæmia, 781
Gairdner Foundation Awards of Merit, 519
Galactic Radio Emission between 10 Mc/s and 1.5 Mc/s · Spectrum of the (G R. A Ellis *et al*), 1079
Galactose Metabolism : Phenotypic Differences among Tissues of a Patient with Congenital Galactosæmia (Y. J Topper, L. Laster and S. Segal), 1006
β-D-Galactoside · 6-O-Acetyl o-Nitrophenyl (Y. Z Frohwein), 775
Gale, Muriel M , *et al.* . Advantages of Iodine-125 for Studying Thyroid Function in Experimental Animals, 1065
Gallango, M L., *et al* : A New Variant of Human Transferrin in a Venezuelan Family, 477
Gallotannin and Pyrethrin in the Flowers of Peony (I. Chmielewska and Z Kasprzyk), 776
Galloway, Dr. R. B. . Appointed lecturer in Philosophy, 622
Game Animals in the Kruger National Park, 19
γ-Emitting Nuclides in Milk since 1960 (R. E. Bentley), 738
Gamma-Globulin : An Examination of HeLa Cancer Cells for Production of (A Z. Budzyński *et al*), 892
γ-Ray-induced Formation of Gold Sol from Chloroauric Acid Solution (H. Fujita, M. Izawa and H. Yamazaki), 666
γ-Ray Spectrometry : Rapid Determination of Tungsten in Steel by Neutron Activation and (Minoru Okada), 1088
Gamma-Recoil Products from the Neutron Irradiation of Colloidal Silver (W. Parker), 763
Gandhi, O P. . Doppler Frequency Multiplication by a Semiconductor Depletion Layer, 884
Gangolly, S R., and K. M. Pandalai : Vegetative Propagation in the Coconut, 905
Ganguli, Prasanta K., and Amrita L. Bhattacharyya : Concentration Dependence of Sedimentation Coefficient of Deoxyribonucleic Acid with added Sodium Chloride, 1201
Garcia, J., *et al.* : Immediate Detection of X-rays by the Rat, 1014
Garcia, J. F , and J. C. Schooley : Erythropoietic Stimulation in the Hypertransfused Guinea-Pig following Injections of Human Urinary Erythropoietin, 279
Gardner, F. H., *et al* . Comparative Metabolism of Hæmoglobins A and F in Thalassæmia, 781
Garland, P B , and P. J. Randle : A Rapid Enzymatic Assay for Glycerol, 987
Garn, S. M , and C G. Rohmann X-linked Inheritance of Developmental Timing in Man, 695
Garner, H. V. Advances in Agronomy, Vol 13, *review*, 6
Garratt, P. G., *et al.* : Radiation-induced Solid-State Polymerization of Acrylonitrile and Acrylamide in the Presence of an Electric Field, 574
Garrett, Dr. S. D : *Obituary* of Walter Buddin, 811
Gartside, J. M , *et al.* · Effect of Carbon Dioxide and Diphenylhydantoin on the Partition of Triiodothyronine labelled with Iodine-131 between the Red Cells and the Plasma Proteins, 275
Gartside, R , *et al* : Activities of Various Concentrations of Triamcinolone Acetonide, 486
Gas Chromatography (C. G. Scott), 817
  Resolution in (R. A. Hurrell and S G. Perry), 571
  Self-sustained Discharge Detector for (Arthur Karmen and Robert L. Bowman), 62
  Ultramicrodetermination of Chemical Structure of Organic Compounds by (M. Beroza), 768
Gas Chromatographic Analysis of C_1-C_4 Hydrocarbons with open Tubular Columns (W Averill and L S Ettre), 1198
Gas Chromatography Capillary Columns . Wetting Phenomena in (F Farré-Rius, J. Henniker and G Guiochon), 63
Gas Chromatography Discussion Group Meeting held September 1962, 817
  Amalgamated with the Institute of Petroleum, 724
Gas Chromatography of Benzene Clathrate . Pyrolysis and (V. M. Bhatnagar and J H. Dhont), 769
Gas–Liquid Chromatography · Analysis of Fatty Acids of Continuously Cultured Mammalian Cells by (John J. Boyle and Ernest H. Ludwig), 893
Gas–Liquid and Liquid–Liquid Interfaces Bibliography of (Joseph Crosfield Ltd), 1041
Gaseous Mixtures Amine-Alcohol Systems · Hydrogen Bonding in (D J Millen and J. Zabicky), 889
Gaseous Optical Masers (Dr. J. H. Sanders), 943
Gases by Blood-acidification in the Swim-bladder of the Eel : Action of the Rete Mirabile in the Secretion of (J. B Steen), 906
Gasic, G., and T. Gasic : Removal and Regeneration of the Cell Coating in Tumour Cells, 170
Gasic, T., and G. Gasic . Removal and Regeneration of the Cell Coating in Tumour Cells, 170
Gass, Dr. George H., and Robert T. Jarrett : An Experimental Evaluation of the Association of Pregnancy and Acute Leukæmia, 139
Gasterosteus aculeatus L. and *Gasterosteus pungitius* L. : *Dermocystidium gasterostei* n. sp., a Parasite of (Dr. E. Elkan), 958
Gasterosteus pungitius L. : *Dermocystidium gasterostei* n. sp., a Parasite of *Gasterosteus aculeatus* L. and (Dr. E. Elkan), 958
Gattani, M. L. : A Technique for inoculating Wheat with Rusts for Glass-house and Test-tube Culture, 190
Gause, G. F , and A V Laiko : Autonomy of Protein Synthesis in Mutant Staphylococci with Impaired Respiration, 167
Gauthier, A. J., *et al* : Modified Equipment for Measuring Changes in Frozen Fish by Love's Cell Fragility Method, 144
Geacintov, N., *et al* : Luminescence in Plastics, 1089
Gear, A. E , and J A. Bastin . A Corrugated Model for the Lunar Surface, 1305
Geiger, W. B., and J. Mandel : Quasi-Cholinergic Action of Acetylating Agents, 1106
Geiger-Muller Counters : Photoelectrons and their Back Diffusion in Self-quenching (R. M Chaudhri and M. M. Chaudhri), 664
Gel Filtration Estimation of Molecular Weights of Proteins by (Dr. P. Andrews), 36
Gene Structure . A Theory of S (Dr. K. K. Pandey), 236
Gene Synthesizing Deoxyribonuclease in the Polyhedral Pre-viral Genome (Kazuo Yamafuji and Fumiko Yoshihara), 1340
General Cytochemical Methods, Vol. 2 (edited by Prof. J. F. Danielli), *review* by Dr R Barer, 863
General Studies in Technical Colleges, 627
Generalized Hartley-Ross Unbiased Ratio-Type Estimator (B. V Sukhatme), 1238
Genetian Violet and on the Anti staphylococcal Activity of Neomycin : Effect of Various Bile Salts on the Anticandidal Activity of Amphotericin B and (S. S Schneierson *et al*), 909
Genetic Control of Tolerance to Tetra- and Penta-Chloronitrobenzene in *Hypomyces solani f cucurbitae* (S. G. Georgopoulos), 359
Genetic Processes . Recent Developments in the Chemistry of, Symposium to be held in Bradford, 938
Genetic Recombination in a Blue-Green Alga . Apparent (H. D. Kumar), 1121
Genetics · Dr J. C Bowman appointed honorary lecturer in, 418
Genetics and Developments New Patterns in (Prof C. H. Waddington), *review* by Dr. E. M Deuchar, 863
Genetics of Mechanism of Segregation and Disjunction at Meiosis in Man : Incidence on (Fr. Twiesselmann *et al*), 1232
Genotrophs (Flax) Induction, Reversion and Epitrophism of (Dr. Alan Durrant), 1302
Geochemical and Geological Evidence for the Origin of Darwin Glass (Dr. S R. Taylor and M Solomon), 124
"Geological Aspects of Commonwealth Economy" The Eleventh Inter-university Geological Congress, 1157
Geological Aspects of the Origin of Life on Earth (Prof. M. G. Rutten), (Elsevier Monographs · Geo-Sciences Section Subseries : Geology), *review* by Prof. J. D. Bernal, 850
Geological Survey of Great Britain · *Summary of the Progress of the Geological, Survey of Great Britain and the Museum of Practical Geology for the Year* 1961, 814
Geology : Dr. B G. J Upton appointed lecturer in, 622
  Dr A E. Wright appointed lecturer in, 938
Geology Museum (University of Edinburgh) Miss H. C Nibbet appointed curator, 622
Geology of the Atlantic and Gulf Coastal Province of North America (Grover E. Murray), *review* by Dr. H. Dighton Thomas, 4
Geology of the South-West of England, 219
Geology and Geophysics in the U.S.S.R. (Prof S I. Tomkeieff), 941
Geomagnetic Disturbances Associated with the Nuclear Explosion of July 9 (Dr P. R Pisharoty), 822
Geomagnetic Field and its Correlation with Stratospheric Winds . Possibility of *a* 26- or 27-Month Periodicity in the Equatorial (F. D Stacey and P. Westcott), 730
Geophysics . Symposium on "Equatorial Geophysics", 1042
Geophysics in the U.S S R. Geology and (Prof. S I. Tomkeieff), 941
Geophysik und Technik · Zahlenwerte und Funktionen aus Physik, Chemie, Astronomie, (Landolt-Bornstein), Band II, Teil 4, *review* by S. P. Cooper, 868
George, W D . Third International Conference on Precision Electro-magnetic Measurements, 921
Georgopoulos, S. G. : Genetic Control of Tolerance to Tetra- and Penta-Chloronitrobenzene in *Hypomyces solani f. cucurbitae*, 359
Gerber, G B., *et al.* · Biosynthesis of Creatine by the Kidney, 286
Gercken, Dr. G , *et al* : Lack of Activation of Phosphorylase by Adrenaline during its Physiological effect on Intestinal Smooth Muscle, 944
Gerencser, V F , *et al* : Inhibition of Bacterial Growth by Magnetic Fields, 539
Gery, I , and A. M Davies · Immunotolerance to Heterologous Heart in the Rat, 184
Gezon, Horace M., *et al.* · Ribonucleic Acid Synthesis in Chloramphenicol-treated *Shigella*, 66
Ghizari, E., *et al.* : Influence of Ionizing Radiation on Glutaminase Activity in Mouse Brain and Liver, 1223
Ghose, T., *et al.* · Kidney Specific Antigen and its Species Distribution, 385
  Uptake of Proteins by Malignant Cells, 1108
Giant form of *Chlorella pyrenoidosa* (M. R-López and R R-Candela), 691
Gibberella zeae · Isolation of an Anabolic, Uterotrophic Compound from Corn infected with (Martin Stob *et al.*), 1318
Gibberellic Acid : Inhibition of Fruit-Bud Formation in Apple with (C G. Guttridge), 1008
Gibberellin-like Activity of Kudzu Vine Extract (M. A. Manzelli, N. Adler and J M. Merritt), 492
Gibberellin-like Substance by *Arthrobacter globiformis* : Production of a (H. Katznelson *et al.*), 1012
Gibberellin-like Substances in Plants (J Kato, W. K. Purves and B. O. Phinney), 687
Gibbons, R. A , and D. Tampion : Effect of Mucus on the Swimming-Rate of Sperms, 290
Gibbs, Josiah Willard : Thirty-sixth lecture to be given by Prof C. E. Shannon, 724
Gibbsite as a Primary Weathering Product of Acid Igneous Rocks : Formation of (J P. Watson), 1123
Gibson, Sir Donald : Appointed Director-General of research and development, Ministry of Public Building and Works, 724
Gibson, Dr. J B., and Prof. J. M. Thoday : An Apparent 20 Map-Unit Position Effect, 661
Gibson, J. F. : Unpaired Electron in Nitroso-*bis*-(dimethyldithiocarbamato)-iron(II), 64
Gilbertsen, Dr. A. S., *et al* : Enterohepatic Circulation of Unconjugated Bilirubin in Man, 141
Gilfillan, Dr. R. F., *et al.* : Sialoresponsin : Neuraminic Acid-containing Substance(s) which Accumulates in Chorioallantoic Fluid during the first minutes of Virus Infection, 649
Gillette, K. G., *et al.* : Isolation of an Anabolic, Uterotrophic Compound from Corn infected with *Gibberella zeae*, 1318
Gillissen, G. : Histamine and its Possible Role in Cyrolysis of White Blood Cells in Guinea Pigs sensitized with Tubercle Bacilli, 590

Iso-Butyric Acid in Silage (D J. C Jones and D. J. Fricker), 1211
Isocitrate Lyase in Synthesis of Oxalic Acid in Plants : Role of (Dr A. Millerd et *al*), 955
Isolation from Cottonseed Oil of a Halphen-negative Fraction which causes Pink-'White' Discoloration in Stored Eggs (R. J. Evans, S. L. Bandemer and J A. Davidson), 1315
Isolation of an Anabolic, Uterotrophic Compound from Corn infected with *Gibberella zeae* (Martin Stob), R. S. Baldwin, John Tuite, F N Andrews and K G. Gillette), 1318
Isolation of Antigenic Fractions from *Bordetella pertussis* by means of Lysozyme (Z Pusztai, I. Joó and E Eckhardt), 296
Isolation of Aspartic Acid Activating Enzyme from Bakers' Yeast (Esam Moustafa and George Petersen), 377
Isolation of and Direct Analysis of Uncontaminated Muscle Cell Contents (R. M. Love), 593
Isolation of Nuclei from Animal Cell Suspensions (H W Fisher and H. Harris), 910
Isolation and Phosphorylation of a New Hydrolysis Product of 2-Methyl-Δ^2-Oxazoline (R Greenhalgh), 267
Isomers of Farnesol Juvenile Hormone Activity of (R. T. Yamamoto and M Jacobson), 908
Isopropylnoradrenaline and Noradrenaline in Man Peripheral Vascular Effects of Mixtures of (W. E Glover et *al*), 999
Isosepiapterin : Structure of Sepiapterin and (H S. Forrest and Saburo Nawa), 372
  Synthesis of the Yellow Pteridine, (S Nawa and H. S Forrest), 169
Isotactic Polypropylene Oxide : Fractionation of Partially (C. Booth et *al*.), 772
Isotopic Composition of Strontium in Carbonatites (J. L. Powell, P. M Hurley and H W Fairbairn), 1085
Isotopic Oxygen Incorporation in Xanthophylls of *Spinacea oleracea* Quantasomes (E A Shneour and Prof. M Calvin), 439
Isotropic Exchange Integral for Cupric Acetate Monohydrate Crystals (A Mookherji and S C Mathur), 370
Isozymes in the Developing Rat Brain : Lactate Dehydrogenase (V. Bonavita et *al*), 576
Istiophoridae along the South Atlantic and Mediterranean Coasts of Spain : Presence of (J Rodriguez-Roda and J. K Howard), 496
Italian Rock Carvings, 417
Ito, M., et *al*. : Injection of Alkaline Cations into Cat Spinal Motoneurones, 1319

Phoma Species in the Rotting of Jute : Role of *Dendrophoma* and (S. N Basu and J. P Bhattacharyya), 86
Phosphate : Passive Transport in the Renal Reabsorption of Inorganic Phosphate in the Dog (L. C Isaacson), 273
Phosphate Compounds in Plant Extracts : Determination of Certain (J. Barker et *al*), 1115
Phosphatide Acyl Hydrolase (Phospholipase *A*) : Positional Specificity of (G. H De Haas et *al.*), 68
Phosphatidyl-Glycerol : Characterization of Lipoamino-Acids as *O*-Amino-Acid Esters of (Dr. Marjorie G Macfarlane), 136
Phosphatidyl Serine on Blood Clotting with Particular Reference to the Russell's Viper Venom Time . Effects of Intravenous Phospholipid containing (Dr J F. Mustard et *al*), 1063
6-Phosphogluconate Dehydrogenase Activities in Erythrocytes of Monkeys infected with *Plasmodium knowlesi* : Glucose-6-Phosphate and (K. A. Fletcher and B G. Maegraith), 1316
Phospholipase A : Mechanism of the Ether Activation of (R. M. C. Dawson), 67
  Positional Specificity of Phosphatide Acyl Hydrolase (G. H. De Haas et *al.*), 68
Phospholipase Activity of Staphylococcal Toxin (B. J. Magnusson, H M. Doery and J. Gulasekharam), 271
Phospholipid Effects of Intravenous Phospholipid containing Phosphatidyl Serine on Blood Clotting with Particular Reference to the Russell's Viper Venom Time (Dr J. F Mustard et *al.*), 1063
Phospholipids of Brain and Liver Dispersions : Incorporation of 1-*O*-Phosphoryl-2-Dimethylaminoethanol and Phosphorylcholine into the (Dr G B Ansell and Dr. T. Chojnacki), 545
Phospholipids with Phosphorus-32 in Rat Liver Homogenates : Labelling of (F. D. Collins), 671
Phosphoproteins and Sodium Transport (J. D Judah, K. Ahmed and A E. M. McLean), 484
Phosphorus-32 Recoils in Potassium Chloride Crystals : Annealing Behaviour of (J. S. Butterworth and I. G Campbell), 982
Phosphorus-32 in Rat Liver Homogenates : Labelling of Phospholipids with (F D Collins), 671
Phosphorus in Wether Lambs : A Reciprocal Relationship between the Urinary Excretion of Magnesium and (H. R. Crookshank and J. D Robbins), 1343
1-*O*-Phosphory-2-Dimethylaminoethanol and Phosphorylcholine into the Phospholipids of Brain and Liver Dispersions : Incorporation of (Dr G. B. Ansell and Dr. T. Chojnacki), 545
Phosphorylase by Adrenaline during its Physiological effect on Intestinal Smooth Muscle : Lack of Activation of (Prof E. Bueding et *al*), 944
Phosphorylation (Oxidative) . Ability of Some Antirheumatic Drugs to uncouple (M. W. Whitehouse and J. M Haslam), 1323
Phosphorylcholine into the Phospholipids of Brain and Liver Dispersions : Incorporation of 1-*O*-Phosphoryl-2-Dimethylaminoethanol and (Dr. G. B. Ansell and Dr. T. Chojnacki), 545
Phosphorylcreatine as Energy Supplies for Single Contractions of Working Muscle Chemistry of Muscle Contraction : Adenosine Triphosphate and (Dr D F Cain et *al.*), 214
Photo and Thermoelectric Effects in Semiconductors (Jan Tauc), International Series of Monographs on Semiconductors, Vol. 2, *review* by Dr. A. A Shepherd, 846
Photoelectrons and their Back Diffusion in Self-quenching Geiger-Muller Counters (R. M Chaudhri and M. M. Chaudhri), 664
Photographic Reproduction : Symposium on "Quality in Photographic Reproduction", Royal Photographic Society of Great Britain, 322
Photophore and Eye Movement in the Euphausiid *Meganyctiphanes norvegica* (G. O. Sars), (M G Hardy), 790
Photophosphorylation : Oxygen Dependency of *in vivo* (A. R. Krall and Elaine R Bass), 791
Photoreactivation after Division (John Calkins), 686
Photo-sensitive Cell : Frequency of Ciliary Beat measured with a (T. Dalhamn and R. Rylander), 592
Physical Chemistry : Prof P. Gray appointed to a personal chair in, 936
  Dr. R. E. Richards appointed reader in, 622
  Dr L. E. Sutton appointed reader in, 622
Physical Hydrogen Embrittlement of Steel at Elevated Temperatures (G. H. Broomfield), 824
Physical Significance of Michaelis Constants (Keith Dalziel), 1203
Physics : Prof E R Andrew appointed to the chair of experimental physics and in 1964 Lancashire Spencer professor of physics, 720
  Dr. G. E. Bacon appointed to the Chair of, 938, 1268
  Dr. P. S. Farago appointed to a Readership in, 622
  Prof R. Peierls elected to the Wykeham Professorship of, 1038
  Dr A K. Walton appointed lecturer in, 418
  A Course of Selected Lectures in Astronomy, Space Rocketry and (Journey Through Space and the Atom), (edited by Prof. S. T. Butler and Prof. H. Messel), *review* by D G. King Hele, 867
  Solid State (Dr. G. V. Chester and Dr. A. Howie), 119
Physics for Electrical Engineers (Prof. W. P. Jolly), *review* by Prof. A. H. M. Arnold, 848
Physik, Chemie, Astronomie, Geophysik und Technik : Zahlenwerte und Funktionen aus (Landolt Bornstein), Band II, Teil 4, *review* by S. P. Cooper, 868
Physiological Anticoagulating System : Reflex Nature of the (Prof. B. A. Kudrjashov and T. M. Kalishevska), 647
Physiology : Dr J. T. Eayrs appointed to the Fitzmary Chair of, 938
Phytohæmagglutinin In Short term Tissue Cultures : Cytochemical Observations on the Effect of (Dr. D. Quaglino et *al.*), 338
Phytylation of Chlorophyllide and the Formation of Lamellæ in Chloroplasts (S. Klein), 992
Piante Medicinali : Chimica Farmacologia e Terapia, Vol 1, Da Dr. Benigni, Dr. C. Capra e Dr. P. E Cattorini, *review* by Dr. F N Howes, 609
Pictorial Perception *South African Journal of Science*, 58, No 7, July 1962, 621
Pig and Rat Livers : Oxidation of Vitamin A_1 and Vitamin A_2 Aldehydes to the Corresponding Acids by Enzymes from (M. S Bamji et *al.*), 672
Pigeon Breast Muscle Mitochondria following Nerve Section : Biochemical Changes in (E Carafoli et *al.*), 1101
Pillis, I., and M Fuzi : Production of Opacity in Egg Yolk Medium by *Listeria monocytogenes*, 195
Pindell, M H, and W. T. Bradner : Antitumour Properties of Phleomycin, 682
Pine : Deoxyribonucleic Acid Synthesis or Turn over in Non-dividing Pollen Cells of (Robert G Stanley and L. C. T. Young), 1228
Pineal Body Extract : Electrophoretic Pattern of the Soluble Proteins of a (A. Fajer et *al.*), 274
Pinkerton, Mary, et *al.* A 6 Å Model of Triclinic Lysozyme, 1178
Pipes : Genesis of Volcanic Pipes by Fluidization, 1041
Pisharoty, Dr. P. R. : Geomagnetic Disturbances Associated with the Nuclear Explosion of July 9, 822
Pisum Roots : Action of some Acenaphthene Derivatives on Mitosis in (W. G. H Edwards), 688
Pitt, B. M : Oxidation of Phenylpyruvates to Aromatic Aldehydes and Oxalate, 272
Pituitary deprived Female Rats : Functional Activity of the Anterior Pituitary after Prolonged Cultivation *in vitro* and Transplantation into (P. N Martinovitch et *al.*), 89
Plane Strain : Solution of Boundary Value Problems in (N Louat), 1081
Plankton from the East African Area of the Indian Ocean (J Wickstead), 1224
Planning, 28, No 466, 29 October, 1962, *Location of Industry*, 1154
  28, No. 465 ; October 1962 : *The Negotiations on Political Union*, Prepared by Michael Palmer, 725
  28, No. 464 , August 1962 : *Cartel Policy and the Common Market*, 725
Plant Communities of the Scottish Highlands . A Study of Scottish Mountain, Moorland and Forest Vegetation (Dr. Donald N McVean and Dr. Derek A Ratcliffe), (Monographs of the Nature Conservancy, No 1), *review* by Prof. John Walton, 206
Plant Extracts Determination of Certain Phosphate Compounds in (J Barker et *al*), 1115
Plant Growth Regulators on Starch Degradation : Effects of Kinetin and Other (D. Boothby and S T. C Wright), 389
Plant Nutrition : Dr. J. L. Harley appointed reader in, 622
Plant Physiology : Annual Review of, Vol 12 (edited by Leonard Machlis, in association with Winslow R. Briggs), *review* by Prof. W. Stiles, 861
Plant Protein Agar, a Medium for the Isolation and Estimation of Proteolytic Organisms in Grassland Soils (E Grossbard and D. M Hall), 1119
Plant Viruses : A Conspectus of Aphids as Vectors of (J. S Kennedy, M. F Day and V. F. Eastop), *review* by Bruce Johnson, 1246
Plants . Dehydration induced Synthesis of Nucleic Acids and Changing of Composition of Ribonucleic Acid : a Possible Protective Reaction in Drought-resistant Plants (B. Kessler and J. Frank-Tishel), 542
  Gibberellin-like Substances in (J. Kato et *al*), 687
  Mineral Salts Absorption in (Dr J F Sutcliffe). International Series of Monographs on Pure and Applied Biology. Division : Plant Physiology, Vol 1, *review* by Prof W Stiles, 507
  Role of Isocitrate Lyase in Synthesis of Oxalic Acid in (Dr. A Millerd et *al.*), 955
  Wintering of (I M Vasil'yev), *review* by Dr R. G Hurd, 918
Plants of Benzoic Acid to Salicylic Acid and its *β*-*d*-Glucoside : Conversion in (H. D. Klambt), 491
Plants related to Variety and Cation-Exchange Capacity : Resistance to Aluminium and Manganese Toxicities in (P. B. Vose and P. J. Randall), 85
Plasma by White Cells, Platelets and Leukæmic Cells : Levels and Uptake of Ascorbic Acid from (K. W. Denson and J D M. Richards), 1218
Plasma Citrate of Treatment of Primary Hypothyroidism with Triiodothyronine . Effect on the (R. D. Cohen), 486
Plasma (Human) . Hormones in (edited by Dr. Harry N Antoniades), *review* by Prof. A. S. Parkes, 505
Plasma Proteins : Effect of Carbon Dioxide and Diphenylhydantoin on the Partition of Triiodothyronine labelled with Iodine-131 between the Red Cells and the (C. Osorio et *al.*), 275

Plasmodium knowlesi : Glucose-6-Phosphate and 6-Phosphogluconate Dehydrogenase Activities in Erythrocytes of Monkeys infected with (K. A. Fletcher and B. G. Maegraith), 1316
Plastics . Exhibition of "Centenary of Plastics 1862-1962", 19
  Graduate Plastics Programme at Princeton University, 418
  Library Association, *Special Subject List* No 38, 321
  Luminescence in (G Oster *et al.*), 1089
Platelets and Leukæmic Cells : Levels and Uptake of Ascorbic Acid from Plasma by White Cells, (K W. Denson and J D M. Richards), 1218
Platinum Electrodes using a Radiotracer Method : Determination of the Adsorption of Ethylene on (H. Dahms et *al.*), 1310
Platypodidae . The Biology of Malayan Scolytidae and (F. G. Browne), (Malayan Forest Records, No. 22), *review* by Dr. C J Taylor, 1246
Plausibility of the Ribonucleic Acid Code (S. W. Golomb), 1228
Playfair, J H. L , et *al* . Development of the Thymus in the Human Fœtus and its Relation to Immunological Potential, 238
Pleistocene Climates and Cultures in North-Eastern Angola (Dr. E. M van Zinderen Bakker and Dr. J Desmond Clark), 639
Pleura by Implantation of Dusts in Laboratory Animals · Experimental Production of Mesothelial Tumours of the (J. C. Wagner), 180
Pneumococcus Appearance of Streptomycin Resistance following the Uptake of Transforming Deoxyribonucleic Acid in (Dr. H. Ephrussi-Taylor), 748
Poikilothermous Animals · Temperature and Life-span in (Prof. Richard F Shaw and Beauregard L. Bercaw), 454
Poisner, A M , and W. W Douglas · Importance of Calcium for Acetylcholine-evoked Salivary Secretion, 379
Poisonous (and Medicinal) Plants of Southern and Eastern Africa : Being an Account of Their Medicinal and Other Uses, Chemical Composition, Pharmacological Effects and Toxicology in Man and Animal (Prof John Mitchell Watt and Dr Maria Gerdina Breyer-Brandwijk), second edition, *review* by Dr F H. Howes, 609
Polak, P . Appointed lecturer in Mechanical Engineering, 418
Polarograph Coiled Cathode Oxygen (R A. Butler *et al*), 781
Polarographic Activity of Proteins as a Function of the Dilution of Aqueous Solutions (Dr Lj Ševaljević), 1058
Polarography : Progress in (edited by P Zuman with the collaboration of I. M. Kolthoff), Vols 1 and 2, review by Dr D T Lewis, 1023
Politics Science and the Nation · Policy and (J S Dupré and S A Lakoff), 302
Politics · Science and the Nature of, 301
  The Nature of (Prof. J D B. Miller), 301
Politics of the Kula Ring : An Analysis of the Findings of Bronislaw Malinowski (J. P. Singh Uberoi), *review* by Dr R. F Fortune, 865
Poljak, R J , et *al* Structure of Lysozyme, 1173
Pollen Cells of Pine . Deoxyribonucleic Acid Synthesis or Turn-over in Non-dividing (Robert G Stanley and L C T Young), 1228

TRAINING AND RESEARCH IN FOOD SCIENCE

FOOD science, though the term is of recent origin, has travelled a long road since a hundred years ago when an Act of Parliament to prevent the adulteration of food and drink reached the Statute Book. Many side-roads—and perhaps not many cul-de-sacs—have been opened up on the way, and now the subject spreads itself across a bewildering complex of scientific disciplines; agriculture, chemistry, physiology, biochemistry, pharmacology, toxicology and pathology are only the more obvious. The subject has attained a position of prominence in the activities of Government, industry and higher centres of learning; and, again rightly, is arousing considerable public interest.

The nation spends £5,000 million annually on food—about a third of all personal expenditure in the United Kingdom. It is not easy to estimate spending by industry on food research, mainly because of the complexities already referred to and the diversity of effort, but it is unlikely to exceed 0·1 per cent of this, or £5,000,000 per annum. (The total estimated research and development expenditure on food, drink and tobacco in 1959 is given as £5·5 million in the Department of Scientific and Industrial Research *Report on Industrial Research and Development Expenditure* (H.M.S.O. 1960).) The amount spent on food advertising is estimated conservatively at £20,000,000 annually.

A number of larger food and allied firms have good research facilities, and Government and industry between them maintain five research associations dealing with food. In addition, there are other centres wholly maintained by Government and controlled through the Research Councils, and these and many departments of universities and other higher educational institutions are concerned directly or indirectly with research in food science. The productivity of all this effort is not inconsiderable, but some areas of inquiry are inadequately covered or wholly neglected. There has been no systematic study of natural foods or of a wide variety of 'traditional' food additives or contaminants, either from the point of view of toxicity or from the point of view of their other physiological or pharmacological effects. Legislation, much of which is of comparatively recent origin, has made it increasingly unlikely that anyone will wittingly adulterate or compound food with potent noxious substances, or with new potential toxins; but the paucity of knowledge concerning weak toxins and substances with peculiar or delayed toxic effects gives little ground for confidence in the complete safety of our food. Lack of finance is only partly, and not primarily, to blame for these wide gaps in knowledge; lack of organization on a sufficiently large scale (which could mean failure to perceive the importance, or even to recognize the existence, of many problems), lack of positive directives in situations where responsibility for tackling problems is divided and lack of suitably qualified investigators have been the more important factors.

The rapid pace of advance in food technology and in food handling practice, sociological and commercial pressures, and the dictates of fad and fancy, all tend towards increasing sophistication in the preparation of food prior to retail sale More and more food is artificially treated with preservatives, flavourings, colourings, and other agents; the calculated results of labour-saving and added appeal may, therefore, be accompanied by increasing and not so readily ascertained toxic risks. There is no doubt that understanding of the long-term biological effects of these practices is not keeping pace Industry. in all its ramified operations from primary production to presenting food on the consumer's table, no doubt does the best it can within present limits of knowledge to ensure a harmless and wholesome result. But this best often falls a long way short of the desired standard. The crucial question is whether conventional test methods are safe, consistently reliable, and their results sufficiently applicable to man.

The Government and industry are advised in these matters by a group of expert bodies the terms of reference of which effectively cover all the possible hazards likely to arise from what is done to food and put into food, and from food itself. There is a Food Hygiene Advisory Council which advises the Ministry of Health and the Ministry of Agriculture, Fisheries and Food on matters concerning the handling, transport, labelling and advertising of food. The Food Standards Committee, recently reconstituted, works largely through a Food Additives and Contaminants Sub-Committee which considers problems in relation to all substances added to food, whether deliberately or not. A Standing Advisory Committee on Poisonous Substances used in Agriculture and Food Storage ensures that food produced from treated crops contains no harmful residues, and a special research study group is also concerned with pesticides and herbicides and "the needs for further research into the effects of the use of toxic chemicals in agriculture and food storage". The most recent of these bodies to be set up is a Standing Panel on Carcinogenic Hazards in Food Additives and Food Contaminants. The field appears to be under continuous and thorough scrutiny in Great Britain; there are also the regular joint conferences between the Food and Agriculture Organization (F.A.O.) and the World Health Organization (W.H.O.) of the United Nations on the subject of food additives, and much knowledge and advice are available from other countries, some of which, notably the United States, have as yet a more rigorous legislative. if not scientific, approach.

This whole edifice of advisory machinery and safeguards rests ultimately on a foundation of fundamental knowledge of general human physiology and, in particular, of human digestive and metabolic processes, but it is difficult to escape a feeling that this foundation is inadequate. There is no case for lessening the load of the structure; it is the foundation which must be strengthened by greater efforts to widen and deepen the extent of knowledge about what really happens biologically when man assimilates his food with, on occasion, some component which may have immediate or delayed deleterious effects.

A joint F.A.O./W.H.O. Expert Committee on Food Additives meeting in 1957 examined procedures for the testing of food additives to establish their safety for use. It was pointed out that as additives may be taken for the greater part of a lifetime and produce hitherto unsuspected reactions, relatively much higher doses of the additives than human beings are likely to receive should be fed to experimental animals for most or all of their lives. No single pattern of tests will do for all the many additives—hence the Committee could make only general recommendations—and even so, it admitted that absolute proof of non-toxicity could not be established since there may also be occasional cases of idiosyncrasy. The Committee recognized that the best evidence for the safety of food additives must come from human studies, but that because of the obvious difficulties reliance would have to be placed on other methods, among them animal experiments. The Committee suggested that the use of high dosage-levels and the spread of investigations over a number of different species made it reasonable to extrapolate the data to man; but it allowed that there would need to be some margin for species differences in susceptibility, the numerical difference between the relatively small numbers of test animals and the relatively large human population at risk, the greater variety of complicating disease processes in human beings, the difficulty of estimating human intake, and the possibility of synergistic action between different additives and between additives and other environmental factors.

It is possible that the F.A.O./W.H.O. Committee is here putting too little emphasis on the allowances which need to be made for species differences in susceptibility and the validity or otherwise of extrapolation of findings to the human case. In another and closely related connexion, the screening of pharmaceutical products by resort to laboratory animal tests, it has been argued that this is of doubtful value in relation to assessing safety of administration to humans. It has been said that the pharmacological activity and toxicity of drugs vary, both qualitatively and quantitatively, between the widest limits in the diversity of animal species used in medical research; and that similar wide differences occur even between different strains of the same species, and between the sexes.

What will undoubtedly go far to repair deficiencies in our understanding of these problems, and to provide a broader and sounder base for advice and legislation, was the creation in 1960 of the British Industrial Biological Research Association (B.I.B.R.A.). More recent proposals for a food research institute at Norwich may also contribute much in this direction. B.I.B.R.A. has been formed to study the possible effects on health, and to ensure the harmlessness, of substances which may be ingested in food, drink and cosmetics. The Association's main object is the establishment of a biological research station for investigating the effect of substances used in food manufacture, either as processing aids or for flavouring and colouring food, as well as those which may get into food from pesticides, from plant used in food manufacture, from packaging materials, or from utensils.

The new Association, supported equally by industry and by the Government, will clearly have to devote much of its effort to dealing with industry's immediate needs for tests and advice on the safety of particular substances and processes; in the case of smaller firms this is primarily what the industry is paying for; in the case of larger firms, having research facilities of their own, the prevention of costly duplication of basic investigations is probably equally important. Of great interest to industry also is the part the Association can play in simplifying, speeding up and reducing the cost of testing procedures; a comprehensive test of a substance, using several species of laboratory animals and designed to show up any carcinogenic as well as other toxic hazards, can at present cost upwards of £20,000. But the Association is rightly taking a much wider view of responsibility for ensuring that food is safe and known by the public to be safe; a responsibility not in the nature of things so easily attached to any particular section of the food industry—producer, chemical and plant manufacturer, converter and distributor. For apart from the more routine testing function, the Association will engage in research into the basic biological mechanisms underlying the testing methods themselves, and into topics such as comparative toxicology. This programme of more fundamental inquiry might have the very desirable result of improving present testing procedures and devising new ones which will be safer and more reliable. It is very much to be hoped that industry, and indeed other appropriate sources of funds, will recognize the importance of this wider function and be willing to help finance it adequately.

But problems are accumulating more rapidly than they can be investigated and B.I.B.R.A. cannot hope to tackle more than a fraction of them. Other research associations concerned with food might, therefore, consider devoting more attention to fundamental studies. University departments might also help, and the colleges of technology, some with long-established interests in food science and much good relevant research to their credit, could increase the significance of their contribution. Many other centres—Governmental, industrial and private—could also aid in the better understanding of matters such as the biochemistry of food metabolism, comparative toxicology and pathology. The whole methodology of testing procedures, as already implied, needs much closer study, and, since the facilities for animal experimentation available to B.I.B.R.A. are likely to be limited for several years, this is a field which should commend itself to centres already well equipped for animal studies.

Yet more pressing still than the inadequacy of material facilities is the acute shortage of scientists with the necessary qualifications and experience, particularly in the fields of pathology and pharmacology. Furthermore, a good grounding in any one discipline is rarely adequate, by itself, for grappling effectively with the many complex problems which arise in this general field. Often it is necessary for teams of specialists from different disciplines to work together on such problems. From co-operative efforts of this kind individuals with some specialist knowledge in several disciplines eventually emerge, but at present these constitute a *rarum genus*.

Able specialists in physical, biological, medical, or veterinary science have seldom shown a special inclination to engage in fundamental food science studies, nor to fit themselves better for these by seeking appropriate training or experience. They may often harbour the unfounded suspicion that subsequent career prospects may not be especially attractive. It is timely, therefore, that the Nuffield Foundation has now announced that it is prepared to offer a number of scholarships to encourage science, medical and veterinary graduates to acquire wider experience and expertise in fundamental food science. Details of these awards appear on p. 20 of this issue, and it must be hoped that suitable graduates will avail themselves of these new opportunities. Those who do can certainly look forward to finding ample scope for fundamental research, and to progressively improving career prospects. Industry, Government agencies, and the academic world are likely to make increasing demands for high-calibre people with wide experience; the Nuffield scheme should succeed in stimulating a greater flow of able people into the field to meet this demand.

The scheme can do little to alleviate the general shortage of food scientists as such, designed, as it is, to meet a critical need only in the higher echelons where it is increasingly important and urgent for more work to be done on basic metabolism, toxicology, and pharmacology, and the methodology of testing. The shortage of food scientists and technologists in general is another and very great problem, and it is quite clear that present facilities for training greater numbers of graduates are inadequate. A symposium at last year's meeting of the British Association for the Advancement of Science showed that the present output, plus planned extensions in the United Kingdom, would by no means keep pace with the increasing demand over the next few years, and this assessment takes no account of the vast training needs overseas which, at least so far as the Commonwealth is concerned, should be partly met by Britain. The scale of the requirement for more training facilities in the United Kingdom, even for internal needs, is quite beyond the resources of any private finance and must be a charge on the Government, but the Nuffield scheme could well provide some of the inspiration and leadership which will be essential.

The Nuffield scholarship awards should also be helpful to existing research institutions concerned in one way or another with food science. It is sometimes observed that Government research establishments and the research associations suffer from the evils of having such high proportions of permanent staff; there is all too little mobility among the established staff and too few opportunities for temporary attachment of visiting research workers. These factors tend to lead to a poverty of fresh ideas. A woeful reluctance, sometimes refusal, on the part of universities to allow graduates working in these organizations to register for higher degrees can mean further impoverishment. It will be possible, however, for holders of the Nuffield awards to receive part of their training in a research institute or a research association (whether or not they can there study for a Ph.D.), and being selected for their ability and imaginative outlook they should be an asset to any host institution. Their numbers, necessarily small, will perhaps have little enough overall impact; but other ways should be found to follow the Nuffield lead and create more opportunities for temporary attachments of this reciprocally beneficial kind.

NATURAL RESOURCES AS POPULATION PROBLEMS

The Exploitation of Natural Animal Populations
Edited by E. D. Le Cren and Dr. M. W. Holdgate. (The British Ecological Society, Symposium No. 2.) Pp. xiv + 399. (Oxford: Blackwell Scientific Publications; Springfield, Ill.: Charles C. Thomas, 1962.) 60*s*. net.

FOR thirty years the British Ecological Society has sought to encourage a common outlook on population ecology among workers on different groups of animals, many of whom tend to be partly isolated by their special economic interests in pest control, game management, fisheries and the like. This has been done through the agency of the *Journal of Animal Ecology*, and latterly also through special conferences.

The present Symposium attracted more than a hundred people of very varied backgrounds, from ten countries. Of the twenty-one papers printed in this volume, there are two on land mammal populations (Denmark and Africa), four on seals (Canada and Britain), two on whales (Norway and Antarctic), three on wildfowl and gamebirds (Britain), seven on marine or freshwater fish (mainly from Europe), and three on invertebrates. The last three are on very diverse subjects: British marine benthos, Canadian insects, and American laboratory experiments on waterfleas and algæ. There is also a general discussion, of far less value than the individual papers. The latter also range widely in emphasis from the directly economic manipulation of populations at one end, to quite complex mathematical discussions and models at the other. But there is a fairly coherent skein of common interests running through them: the ways in which populations may be regulated naturally, as well as by man, their fluctuations, age distributions, input and mortality, and so on. The usefulness of such a common forum for such a variegated field of effort is clear enough. The papers are rather unusually clear, full and business-like for conference contributions, and carry most informative bibliographies in their special fields, and the editing has been very capable. The renderings of questions and answers after the papers, though adding a little to clarity, are probably not worth the great labour of rescuing them from oblivion. There is a good index, which is worth perusal in any event as an indication of the remarkable concourse of subjects involved in population ecology: for example, "Giraffe, Glen Esk, *Glossina*, Goats, Gompertz Curve, Goose . . . Grilse, Grimsby, Ground-nut, Grouse".

It might be supposed that the easiest part of population research would be making a complete census of part of the population. But in many instances this is not only the most laborious but also the most difficult technically. An investigation of a Danish roe-deer population, in which individual deer were caught and then released with special marked collars to wear, revealed that something like three-quarters of the whole population would need to be marked, in order to get accurate estimates of the total. The age distribution of a species recurs in these studies as one of the crucial components of the whole picture, and to get this it is necessary to find age indices (such as fish-scales, plumage stages, ear-plugs or annual shell-rings), or else mark animals over some years. To get any notion at all of the changing population structure and movements is a very long and exacting task. Nearly all the investigations described still have large blank patches. The mathematical models being developed, though useful and promising, are mostly far from fitting known facts, let alone predicting unknown ones. The rational exploitation and management of wild populations, therefore, will require many more years of basic research.

C. S. ELTON

THE ATLANTIC AND GULF COAST GEOSYNCLINE

Geology of the Atlantic and Gulf Coastal Province of North America

By Grover E. Murray. Pp. xvii + 692, illus. (New York: Harper's Geoscience Series, Harper and Brothers, 1961.) 24.00 dollars.

THE Atlantic and Gulf Coastal Province of North America is a well-marked physiographical and geological entity extending from Newfoundland to Central America, the part north of Cape Cod being submerged, but the rest partially emerged. Its surface geology is well known, and its subsurface geology is known better than that of anywhere else in the world, because of the intensive drilling for oil which has taken place and because of the numerous geophysical investigations carried out Prof. Murray has brought together the information gleaned from 10,000 papers published on the Province, as well as that from numerous private reports to which he has had access, so that fundamentally this is a factual account with only rare theoretical discussion.

This great coastal entity is an extensive "geosyncline consisting of an irregular mass of Mesozoic and Cenozoic sediments, grossly lenticular in the land-sea dimension and superimposed upon Palæozoic and Precambrian rocks, the surface of which dips generally seaward". These sediments, commonly unconsolidated, vary from some 20,000 ft. along the Atlantic portion to from 40,000 to 50,000 ft. around the Gulf of Mexico. Rightly, the author discusses the areas flanking the Province, since their geology has had a profound influence on it. The basement in fact, is essentially a continuation of those areas both stratigraphically and structurally, and folded and faulted metamorphic, igneous and Palæozoic and Triassic sediments are present. In a chapter on structural geology, the initiation, development and growth of the geosyncline are thought to have been connected with the elevation of the continental platform following the late Palæozoic orogenies and the destruction of the Palæozoic geosynclines. The sedimentary load was probably intimately related to its development—"downbuilding of the geosyncline . . ., once an initial site for deposition was established, seems to have been continually abetted by the load of sediments, a process that has continued to the present day". Thus structurally the Province is essentially one of vertical movement (though compressional movements in Mexico produced the folded area adjacent to the Sierra Madre Oriental) The major fracture zones, which occur in much o the Province, trend north-east–south-west and north-west–south-east, and are aligned with the fracture patterns in the older areas bordering it Control by Precambrian and Palæozoic structure and trends is thus evidenced, and is doubtless rendered by major fractures in the basement rocks.

The salt structures, which occur in the 'deep south and in Mexico, are domes, anticlines and ridge-like diapiric folds of great structural magnitude and o varying height and extent, for example, up to six miles in diameter at the surface. They are described in some detail and their relationship to sediments cap-rock, etc., discussed. The author considers that clusters of them seem to be related to thick salt and extra thick salt overburden and to zones of strike faulting and flexing. There is a long and useful section on regional stratigraphy, with the emphasis on lithology. Upper Cretaceous and later deposit make up most of the surface rocks of the Province especially of the part in the United States, though Jurassic and Lower Cretaceous rocks occur ther below ground and outcrop in Mexico and in a few smal areas in Arkansas, Oklahoma and possibly Alabama The account of the mineral resources is very much condensed, but they are abundant and very important, especially oil and gas. The book concludes with two geographical chapters. The first, on physiography, deals with both the submerged and th emerged areas of the geosyncline, the former with a subdued topography, and the latter with its topography clearly related to its alternating types o rock, the seaward progression of depositional centre and axes, and the progressive tilting of the olde strata. Once again Mexico, with mountains carved out of the uplifted strata, shows contrasts with th rest of the Province. The final chapter deals i summarized form with climate, vegetation and soil —the climate, ranging from tropical wet to humid microthermal, produces different results on th landscape, soils, drainage and vegetation of th various regions into which the coastal plain is divided and hence on the human geography.

With such a comprehensive factual account, covering so large an area and so many aspects, compression the presentation of data is necessary. This does make for easy reading, but the numerous, clear grams facilitate this, and the author has carried his task well. In the result, this detailed study great geosyncline is of importance not only to erican geologists, but also to all who are interested e origin, composition and structure of such major tures of the Earth's crust.

The book is provided with a selected bibliography each section as well as a comprehensive biblio-raphy at the end. It is well produced and clearly rinted.

H. Dighton Thomas

TEXTURES IN SHEET METALLURGY

Textures in Metal Sheets

By Dr. F. A. Underwood. Pp. xii + 148. (London: Macdonald and Co. (Publishers), Ltd., 1961.) 28*s*. net.

The technological importance of texture has recently been emphasized by several new developments. Twenty-five years ago anisotropic properties became commercially useful in silicon–iron transformer core material; about six years ago cube texture was also produced in this alloy. Furthermore, in this past six years many details of processing have become known generally. Less common metals, such as bismuth and uranium, are being used commercially; there is strong interest in their anisotropic properties, particularly where they are subjected to cyclic heat treatment.

Control of texture is important and might arise, for example, through alloying, by the control of a separate phase or by the control of the annealing atmosphere. Much of the information on these aspects has become known recently. While this is not covered in any detail by this book, it does give a useful introduction to the subject. The book is intended either for beginners, who hope to get more involved in the detail, or for those with peripheral interests such as managers, who primarily want to understand results in investigators' reports. Nevertheless, a small extension to the book would have presented a more complete, up-to-date and useful contribution. The lack of very recent references is apparent in several instances.

The elementary level of starting is clear from the introduction and first chapter on preferred orientation. Efforts to keep the book short are laudable but might leave some bewilderment; for example, When are Wulff or stereographic nets used? Methods for determining pole figures are very well described, with the exception of optical techniques. It should be pointed out, however, contrary to p. 55, that instruments are available commercially for constructing pole figures.

Textures are discussed in separate chapters for rolling and recrystallization. They are good summaries but omit some important points. The author pointed out that the work of Bishop and his colleagues gave a reasonably rigorous treatment of rolling textures, but otherwise gave it only a brief mention. The effects of alloying, impurities and atmospheres on recrystallization textures are almost completely ignored.

The last chapter on anisotropy reports measurements on mechanical properties. Earing is discussed in detail. Only in the last few pages is the torque magnetometer mentioned. This is surprising since it is such a useful tool.

It is easy to criticize somebody else's efforts, but it should be clear that most of these comments imply that the book should be longer and more expensive. In fact, the author is to be congratulated on keeping size and cost down to a level at which students can afford to buy it. It is a useful starting point for students in this field; all metallurgical libraries should have a copy.

LIFE: NORMAL AND ABNORMAL

La Vie

Par Jean Rostand et Andrée Tétry. Pp. 468 (960 illustrations). (Paris: Librairie Larousse, 1962.) n.p.

Anyone glancing through this comprehensive, abundantly illustrated and well-produced volume could be forgiven for thinking life was very odd. Scarcely a page is passed that does not contain a picture of the abnormal, from the slightly unusual to the chimerical. So we run the gauntlet from the inevitable mutant *Drosophila* through Siamese twins, the two-headed newt and fork-tailed lizard to albinism and children born with neither hands nor feet. Since the natural freaks are relatively limited, there is a strong reinforcement of the monstrosities produced by selective breeding, experimental zoology and the nuclear device exploded over Hiroshima.

This macabre display of pictures seems scarcely in keeping with the sober and well-informed textual matter, and there may be two reasons for this apparent emphasis on the teratological. First, as every student of taxonomy knows, it is often the exception that sheds more light on, or even lays bare, the truth about the common run. Secondly, as the anatomist and the morphologist have learned, and the behaviourist is beginning to learn, the exceptional or the abnormality is more common than the text-books would lead us to believe. Perhaps there is a third reason, that when the life sciences are treated as exhaustively as they are here there is bound to be a fair proportion of space devoted to these freaks.

Another unusual feature of the book, which has everything to recommend it, is that not only are the various evolutionary theories set forth but so are the arguments against them, even those against the most orthodoxically acceptable. Nothing could be fairer. It is this, perhaps more than anything else, that reveals the true purpose of the book: to bring together within a single volume, as objectively as possible, knowledge that elsewhere tends to be spread over many publications and which, as often as not, reflects the bias of a particular author. The specialist scientist no less than the untutored layman wishing to be abreast with present-day knowledge and theory can expect to find in this book the answers to questions outside his competence. In this, the text is no disappointment. It begins with morality and religion, passes to the consideration of the living cell and the latest knowledge on this important topic, proceeds to sexuality, growth and development, senescence and death, regeneration, the many aspects of genetics, evolution, including that of the Hominidae, and ends with some speculations on the future of the human race. One can but envy the authors their erudition—or the amount they must have learned in compiling the volume—and congratulate them on the fruits of their labours.

Maurice Burton

Progress in Organic Chemistry

Vol. 5. Edited by Dr. J. W. Cook and Dr. W. Carruthers. Pp. viii+172 (Progress Series). (London: Butterworth and Co. (Publishers), Ltd., 1961.) 50*s*.

THE present volume contains a mixture of topics drawn from the fields of natural products, synthesis and reaction mechanisms. Dr. W. A. Waters's lucid chapter, "Homolytic Oxidation Processes", includes sections on autoxidation and one-electron oxidations by ions containing transition metals. "Developments in Hydroxylation of Phenols", by Dr. J. D. Loudon, is a beautifully presented survey of recent preparative methods in this field, including the author's elegant ortho-hydroxylation sequence. "The Chemistry of Dextrans", by Dr. C. R. Ricketts, summarizes present knowledge of the structure and biosynthesis of this polysaccharide which finds important application in blood transfusion. "The Chemistry of the Higher Terpenoids", by Drs. J. A. Barltrop and N. A. J. Rogers, includes some diterpenoid topics of recent interest and an excellent summary of the now very fully explored biosynthesis of squalene and some of its cyclization products. Prof. T. Nozoe contributes the final chapter, "Tropylium and Related Compounds", dealing with the tropylium ion and recent syntheses of tropones and tropolones, including some naturally occurring tropolones. The interesting photo-chemical transformations of colchicine and simpler tropolones and a postscript on the chemistry of heptafulvene conclude this chapter.

Progress in Organic Chemistry aims to summarize areas of the subject where a vantage point has been reached and a degree of order can be seen to emerge. The present volume is a good example. Viewing the series as a whole, the editors' choice of topics has in many cases been timely and the list of contributors includes an impressive number of acknowledged authorities. The non-specialist reader, to whom these reviews are addressed, will look forward to future volumes. He may, however, in view of the price, regard the drastic reduction in size of the present volume with some misgivings. K. H. OVERTON

Advances in Agronomy

Vol. 13. Edited by A. G. Norman. (Prepared under the auspices of the American Society of Agronomy.) Pp. xi+386. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1961.) 86*s*.

THE general agronomist, whose chemistry may not be very near the surface, may find some of the articles in this volume specialized or difficult. Thus, the contributions on physical chemistry of clay–water interaction and that on iron chlorosis in plants are rather heavy going, while the article by the late Dr. Alex. Muir on podzol and podzolic soils will be fully appreciated mainly by pedologists and soil surveyors.

Compared with the above the treatment of subterranean clover is almost bedside reading. This paper naturally comes from Australia, where, thanks to sound experimental work, this crop has put a new face on millions of acres in that country. All aspects of this fascinating crop have been dealt with, and some 250 references quoted. Equally readable is the summary of the barley yellow dwarf virus disease of small grains. The widespread virus diseases of cereals are not well known outside pathology circles. The cause of the disease, an aphis-borne virus, was only discovered in 1951. A very clear pictur
the follow-up of this discovery is given. As so c
happens with the diseases of cereal crops the
hopeful remedy appears to be in the hands o
plant breeder. Stubble-mulch farming is ty
associated with wheat monoculture in arid or
arid areas of the United States, where one of it
functions is to stabilize the soil against erosion
review shows that there are still plenty of prob
to be solved, especially if the practice is to be extenc
to areas with greater rainfall.

There are shorter articles on earthworms, the effe
of which on soil productivity are still somewh
uncertain; and the rather specialized problem of tl
agricultural aspects of the contamination of soils b
petroleum hydrocarbons. H. V. GARNER

An Introduction to Statistical Science in Agricultur

By Dr. D. J. Finney. Second edition. Pp. 21
(Edinburgh and London: Oliver and Boyd, Ltd
1962.) 30*s*. net.

IN the course of the preface the author state
"The book is intended to supplement . . . a
elementary course of lectures for agricultural st
dents who are without mathematical training"–
"The book is designed for consecutive reading, n
for occasional reference"—" . . . my chief aim is
show statistical science as a whole—as a single att
tude of mind to quantitative problems, and not
a series of isolated methods . . .". In all these ai
and intentions Dr. Finney has succeeded admirabl

interest them here. J. A. NELDER

Teach Yourself Atomic Physics

By Dr. J. M. Valentine. (Teach Yourself Book
Pp. 192. (London: The English Universities Pre
Ltd., 1960.) 7*s*. 6*d*. net.

THIS little book is intended to give the laym
an introduction to the ideas of atomic and nucle
structure and of the experimental methods used
atomic physics. The language is simple and math
matics are confined to a few elementary equation
The subject is developed along orthodox lines, begi
ning with kinetic theory and the gas discharge, an
proceeding through the Rutherford–Bohr model
the atom to an outline of nuclear structure an
stability. There follow chapters on particle acceler
tors, detectors, nuclear reactors and nuclear weapon
and finally on the industrial, medical and biologic
uses of isotopes.

The treatment is clear and perhaps more full the
is usual in popular books. But a book with this titl
published in the 1960's, ought to give its reader som
notion of wave mechanical concepts. As it is, he
left with a firm impression that electrons move
circular orbits about a nucleus which can be pen
trated only by particles capable of surmounting t
potential hill around it. K. E. B. JAY

FAITH AND FACT*

By THE RIGHT REV. W. L. GREER

Lord Bishop of Manchester

ow faith is the substance of things hoped for,
e evidence of things not seen." *Hebrews XI.*

nd what is faith? Faith gives substance (or assurance) our hopes, and makes us certain of realities we do ot see." (N.E.B.)

IN 1951, during the meeting of the British Association for the Advancement of Science held in Edinburgh, my friend the late Prof. Donald Baillie gave an address to the Association and others in St. Giles Cathedral. The theme of his discourse was that the most significant part of the conflict between religion and science was not between the scientists and the theologians as two different sets of people, but rather etween two diverse tendencies in the same person, two parts of one man—between the scientist and the heologian existing in the same human breast. t was a tension in the mind of the intellectual etween the honest consideration of factual evidence n one hand, and the haunting claims of faith on the ther.

Now I would wish to pursue this theme a little rther.

We are, I think, all familiar with the fact that in very one of us there are two areas of experience which frequently seem to be in conflict. Indeed we might say they are incommensurate. I refer to the rea of fact and the area of faith.

The area of fact is open to those who have the skill, he intelligence and the insight to observe and o-ordinate natural phenomena. But the area of faith—that is, the area in which God becomes a known eality—is open only to those who (in Prof. Baillie's rase) are "simple-hearted and honest, with something of the wide-open eyes of little children gazing t reality". It is open to those who are not sophisicated by pride, but are obedient and dedicated. The knowledge of God is an assurance, given to humble, honest, obedient hearts. To them, the universe discloses its most vital secrets. What is hidden from the mere intellectual is "revealed unto babes".

Science concerns itself with fact, with the outward, the visible (or potentially visible), with the temporal; and its language is mathematics. Religion deals with faith, with the inward, the invisible, the eternal; and *its* language is poetry. Both are areas of true knowledge, and both are essential to a full human life.

I am, of course, drawing a rough contrast. For these two areas interpenetrate. Science has a faith in the rationality of the universe and in the uniformity of its material constituents, though its faith is a heuristic principle rather than a final commitment. Many of its greatest discoveries have been made in realms for ver invisible to the human eye. Christianity, n the other hand, is vitally concerned with facts, h daily bread, with human actions, with justice, with a historical person who was crucified under a certain Roman Governor, Pontius Pilate, whose name (it is interesting to note) has for the first time been recently discovered on a contemporary Palestinian inscription.

Nevertheless, although these two areas of human experience interpenetrate, the contrast still remains. It is a disturbing, bewildering and perplexing contrast. We venture out on the sea of faith, and fear lest the white canvas of our intellectual integrity may be torn from the mast. We confine ourselves to the study of material things, and the fear takes hold of us that the mind may become a machine, and we may lose something vital in our human inheritance. There is a passage in Darwin's *Autobiography* where he says: "Up to the age of thirty or beyond it, poetry of many kinds, such as the works of Milton, Gray, Byron, Wordsworth, Coleridge or Shelley, gave me great pleasure. I have also said that formerly pictures gave me considerable, and music very great, delight. But now, for many years, I cannot endure to read a line of poetry. My mind seems to have become a kind of machine for grinding general laws out of a large collection of facts, but why this should have caused the atrophy of that part of the brain on which the higher tastes depend, I cannot conceive. The loss of those tastes is a loss of happiness, and may possibly be injurious to the intellect, and more probably to the moral character, by enfeebling the emotional part of our nature". Charles Darwin's experience must have many counterparts to-day when specialization is almost pre-natal.

On the other hand, we can see in the history of religion the disastrous effects of a faith uncontrolled by facts or by rational reflexion. It is recorded of one religious enthusiast that she refused to believe in the physical existence of the city of Jerusalem until it was revealed to her by the Spirit. In poetry and the arts, uncontrolled and undisciplined imagination easily leads to the chaos and the madness of a private world. It is not without significance that Wordsworth was keenly interested in chemistry, and sent the first proofs of his *Lyrical Ballads* to the young scientist Humphrey Davy to correct.

So then, we have these two areas of human experience, distinct, yet not divisible, separate, yet interpenetrating, and in these areas, the pathway to experience presents a contrast, a contrast well described by Pascal when he says "Human things must be known to be loved—Divine things must be loved to be known".

The area of faith, of course, has to do not only with divine things, but also with all things of the spirit, and in particular with human personal relationships. Here we observe at once the inapplicability of scientific method. A young scientist decides that he wishes to get married; he sets about this highly important experiment scientifically and methodically. Having purchased a card index, determined his system of marking for certain desirable qualities, he canvasses all the feminine possibilities. Then, having put the cards in the appropriate machine, he presses the button and obtains the answer. Unfortunately he

---

Substance of the sermon delivered on September 2 in Manchester thedral during the service attended by the Lord Mayor, the Vice-ncellor of the University and the President and members of the tish Association for the Advancement of Science.

discloses his method of procedure to the lady whom the machine has chosen, and she, so far from being pleased, calls him inhuman and sends him about his business. Persons ought not to be treated as things. They, too, must be loved to be known.

I have said that the language of religion is poetry. It is common knowledge that much of the Old Testament is written in Hebrew poetry, and a great deal of the teaching of Jesus Christ seems to have been given in poetic form. But there is more to it than that. There is, I believe, an inner and necessary relationship between religion and poetry. Wordsworth in his Preface to *Lyrical Ballads* expresses well what I have in mind. He writes: “Aristotle has said that poetry is the most philosophic of all writing; its object is truth, not individual and local, but general and operative, not standing upon external testimony but carried alive into the heart by passion. It is the breath and finer spirit of all knowledge; it is the impassioned expression which is in the countenance of all science”. He continues: “The concerns of religion, refer to indefinite objects, and are too weighty for the mind to support them without resting a great part of the burden upon words and symbols. The commerce between man and his Maker cannot be carried on but by a process where much is represented in little. In all this may be perceived the affinity between religion and poetry”. Precisely here is the point of greatest difficulty. The language of religion, which is poetry, is so utterly different from the language of science. We must learn to become bilingual. Perhaps we would, if we were convinced that the other language has real truth to convey.

In the area of experience covered by faith comprising the spiritual relationship between persons, the methods of science have little or no place But that does not mean that the truths there revealed or discovered are illusory or less important. For human happiness they are indeed incomparably more important. They are certainly less exact, less precise, less easily communicable, and less subject to proof. That is but to be expected, for here we are attempting to understand not the part, but the whole. As Walter Bagehot says: “a clear, precise, discriminating intellect shrinks at once from the symbolic, the unbounded, the indefinite The misfortune is that mysticism (and by that he means Christianity) is true”. We can, as some Eastern philosophers do, write off our experience of the material world as illusory—or (and this is the temptation of Western man), write off the Christian Faith as a fairy tale; in either case, human life is impoverished. The two areas of experience must be held together, and the validity of neither denied. That is no easy task in a world dominated by power politics, greed and materialism; but unless it is done deliberately, persistently, and with cost, there is no future eithe for scientific progress or for humanity.

I have spoken of the area of fact and the area faith. “But what is Faith ?” asks my text . . . “Fait gives substance to our hopes and makes us certai of realities we do not see”. It is not belief in spite evidence, but life in scorn of circumstance. I involves committing ourselves and throwing ou actions behind our beliefs. As Hartley Coleridge says “Faith is an affirmation and an act That bids etern truth be present fact”.

That, at a particular time in history, the etern truth became a present fact is precisely what w as Christians, believe. “The word was made flesh an dwelt among us and we beheld His glory (the glor as of the only begotten of the Father), full of grac and truth”. The author of the *Epistle to the Hebre* recognizes this. for in the first verse of the very nex chapter he tells his readers that they must run wit resolution the race for which they are entered, the eyes fixed on Jesus, on whom faith depends fro start to finish.

The secret of this strange and wonderful univers in which we live cannot be contained in any equation only in a person; uniquely, in One Person. An faith depends on that Person, because He was and Himself, the assurance of things hoped for, th evidence of things not seen. It is as we keep our eye fixed on Him, hating the things He hates, loving th things He loves, looking to Him for light to guide u and courage to sustain us—it is as we do these thing that experience validates faith, and we come t know with deeper assurance that He is not only th Way, but also the Truth—a truth no other in kin than that which we seek in our laboratories, yet a a deeper level, on a grander scale, and at a greate cost. That must be so, since it is concerned wit God and Man; God in his glory, love, and power; an Man, his humble origin, and unimaginable destiny.

The British Association has as its object th advancement of science. That is to say, science a commonly understood in its limited meaning. Bu science, of course, really includes all knowledge, an in this age of dazzling discovery, so great are the socia and ethical responsibilities of scientists that I d not see how they can be properly discharged unles we humbly and patiently set ourselves to advanc not only in the accumulation of material facts, bu also in that knowledge that comes through faith Might we not say that—social investment in scienc demands personal investment in faith.

If we do, we shall surely find, as countless other have found, that wisdom is added to our knowledge and that faith (though at the outset a venture increasingly gives assurance to our deepest aspiration and makes us certain of realities we do not at presen see.

MEETING WITH MACHINES*

By PROF. AUREL DAVID

École Pratique des Hautes Études, Sorbonne, Paris

THERE is no difficulty in defining cybernetic medicine; it is a medicine using cybernetic knowledge for diagnosis, treatment or simply for understanding the process of an illness. The weakness of such a definition lies in the fact that it i practically impossible to define the term ‘cybernetics itself. Yet, lack of definition has in no way im paired the promotion of other sciences. If w are able to enumerate a certain number o subjects, apparently dissimilar, connected wit cybernetics, time will show the thread connecting these problems.

---

* Substance of an address delivered at the Second International Congress of Cybernetic Medicine, Amsterdam (1962).

It is already possible to isolate certain more general parts, and specifically cybernetic methods[1]. But these methods are for the present applied to some well-defined and curiously dissimilar points. One could try to give an idea of what cybernetics are by considering those points and examining the spirit in which they are considered.

Cybernetics are connected with questions of:

(*A*) *Loss of determinism*, especially in simple and macroscopic mechanisms connected with an act which is beyond computation, not to be foreseen by its builder himself and giving an irresistible feeling of 'liberty'.

(*B*) *Simulation of functions in a living being* (M. N. Wiener's classical work dealt with this) with an unmistakable preference for those functions which seem the most obscure and farthest from usual material physics. Artificial organs exert an attraction, proportionate to their degree of complexity. The much more difficult question of 'learning' (creation, by the finalized machine, of new parts of itself, new organs or parts of organs, in short, the 'growing' of a machine under pressure of its finality and surrounding) engrosses everybody's mind. The nervous system has been, at the very first, a choice ground. Lastly, the questions which we cannot escape are the subtlest and more immaterial ones: information, negative entropy.

One tries then, so far as possible, to build explicit simulators of the living body: machines that proclaim their name of machine.

(*C*) *Investigation of total efficiency.* This is the definition which Couffignal[2] proclaims, and it can be seen how different this point of view is from the other two and how diverse the definition of cybernetics can be. I shall return to this.

What gives life to the whole study of cybernetics (points *A*, *B*, *C* here) can be expressed in two steps.

(1) Tending to a complete explanation of man, to revealing the miracle, at the risk of causing the miracle itself to disappear.

One can be sure that students of cybernetics have closely followed works about nucleic acids, proteins, submicroscopic morphology of protoplasma, regretting that this insight so near the central mystery has come from radiocrystallography and electronic microscopy and not from cybernetics. The beginning of the destruction of the essential miracle, protoplasm, ought to have fallen by right to the cybernetician.

Then we may remember M. Louis de Broglie's profound remark, declaring that cybernetics will not give entire explanations because of their macroscopic mind when all explanations belong to the microphysical order. Undoubtedly, cybernetics cannot account for everything, and even this subject must invoke the aid of physics, biology, etc. But predilection of cybernetics for what is macroscopic, simple, explainable, throws light on the spirit of this subject.

Perhaps some authors exist who not only try to destroy but also to laugh at the human miracle. There exists a tale—the author's name has slipped my memory—in which a half-insane philosopher is building in a shed a larynx and buccal cavity, set in motion by bellows with huge pieces of leather imitating tongue and cheeks, a mechanism which he hoped to hear some day pronounce in a thundering voice: "Then the word was". It would, no doubt, be possible to do it to-day, but no cybernetician would take any interest in it; for phonation has no longer any semblance of a miracle or mystery. He would be interested in it only if it was a question of improving on Nature (point *C* here), for example, to build a larynx for a wounded person.

The macroscopic vocation of cybernetics does not in any way come from an inclination to laugh at a human miracle by imitating it with pulleys and strings; it comes from a desire of imitating the microphysical, elusive mechanisms of the living being by tangible pieces. If ever the cybernetician is to build a larynx he will not lodge it in a shed. He will make an admirable model of which the scheme, the plan for fitting, and the list of the attendant parts he will possess.

(2) This gives the last precise details about the cybernetic spirit: it does not aim at destroying the miracle for the pleasure of destroying, but to put an end to the impossibility of taking care of an organism which we are not able to understand.

This is, then, real scientific research: the curiosity of knowing and need of knowing, in order to act. Above all, if we can replace the organ which is missing or in danger of being destroyed, by an apparatus built in a factory, that is immortal and ever replaceable. One prefers a machine one can understand to a man one must allow to die because he delights in an unfathomable and capricious miracle.

There is in such an enterprise something passionate and neurosthenic, something of the rescuer who stuns a man who has fallen into deep water in order to quieten him and thus rescue him.

So medicine and cybernetics ought to meet.

How could the meeting be arranged? The physician is, even before being a man of science, a contemplator of the total human miracle which he tries to heal and save. What would remain of the physician if he was a simple machine repairer? The cybernetic spirit seems, on the contrary, to tend to the destruction of man. Each of the three points *A*, *B*, *C* here shows this in its way.

(*A*) The 'losses of determinism' brings the idea of human liberty into ridicule.

(*B*) When a vital function is counterfeited by a machine, either the corresponding human organ is itself only a machine or the living organ—simulated but not reproduced—has indeed something inimitable and miraculous. Then it is a wasted miracle, for the machine obtains, without a miracle, the same results. Why talk of witches' brooms or a flying carpet when aeroplanes exist?

Moreover, the macroscopic simulator goes further in 'dehumanization'. Claude Bernard thought of man as an indivisible whole. Civilized man to-day still follows this medical way of thinking. We do not ignore that (functionally, at least) the eye, or neurone or heart, taken separately, is nothing miraculous. But by adding them together we cross over the threshold to a miracle. There is not here a well-worked-out *gestalt* system, but only this: the eyes, the heart, the nervous system are imperfectly known, and, moreover, bathe in the miracle of their protoplasmic structure and their onto- and philogenetic mode of appearance, which still remains mysterious (at least for some time to come) even if functionally the organ is understood and can be simulated. All organs have a dark zone which increases by addition. A large number of comparatively little-understood organs are merged into an unknowable whole.

Things are not the same with artificial organs. A machine plus a machine is nothing but a larger machine. If the size of the whole surpasses our present power of pre-vision, our ignorance, and not the miraculous character of the whole, must be accused. Never would a judge agree to call a robot 'Sir' (however learned, well educated, loving and clever it may be), the mechanical details of which are thoroughly known and understood. Cybernetics do not acknowledge the *gestalt* and have no dark spots.

(*C*) The study of efficiency is the attribute of techniques; these form an attempt to organize means tending to an end; they look for 'the best way to do work', the most effective way leading to the proposed end. But we may find out in cybernetic efficiency the idea that in a living being, as in a machine, one is always able to calculate the 'best way' where we often see a matter of inspiration, of tricks of the trade, of flash of genius.

If the cybernetician acknowledged this statement, he would seem to set two metaphysical postulates:

(1) There is one 'best way'; a route towards the aim which is better than any other.

(2) It is possible to calculate this route. Then it is calculation which will give the assurance of a better route and not the process of a more human aspect such as inspiration or cleverness. On that score cybernetics, like all other sciences, arrives at the limits of metaphysics.

Yet, just as no cybernetician has ever expressly denied the human miracle, but endeavours to undermine it, inch by inch, so one would not find anywhere the assertion that any technique is calculable. Cybernetics only try to study, one after the other, the ways of working out so-called human routes and replace them—where it is possible—by calculations.

Cyberneticians do not at all question the possibility of choosing aims. (It is, in fact, the attack on this faculty which is the real concern of cybernetics, and this precisely in the indirect manner of the study of means. I am dealing with this point in a book now being written, but we cannot go into it within the limits of this article.) Cyberneticians apply themselves to dismantling the humblest part of the act: the realization of the aim already chosen.

Then, if the techniques used to rely and still often rely on the human being, these also take for granted many data. Starting from this possibility of working up some 'ways to do work' cybernetics try to calculate other ways and itineraries. They do not have to grapple with the techniques of the staff engineer, for, here, the idea has spread for a long time that many things are calculable and are deprived of human mystery. Nevertheless, they are interested in techniques similar to those of the engineer; techniques that set in motion a great number of data, very long-dated pre-visions, ambiguous informations, etc., which until now were entrusted to the inspiration and 'flair' of the great administrator, captain of industry, leader of men, strategist. The success of this cybernetic intrusion in a zone apparently quite human has considerable scientific and philosophical implications.

But now there exist techniques which have a direct effect on human, mysterious techniques, the existence of which puts forward questions next to those set by cybernetics. Such techniques try to shape the man, with the aim of bringing him nearer to perfection: for example, education, law, medicine, etc.

We acknowledge in our heart that only man can touch man. Not that it is not necessary, even here, to surround oneself with all the possible calculations. But we believe that when all has been calculated, when all analyses have been made: (1) no certitude will be reached; (2) the final decision must be taken by the technician himself, a man who will decide—to use simple words—'according to his inspiration and heart'.

Only man can educate, make laws, judge, cure.

Such an axiom is still responsible for the fact that there is no opportunity for the application of human techniques towards the cold cybernetic method. Manufacturers, generals, administrators have accepted this method, perhaps an inhuman but a particularly efficient one. But there exists no such thing as cybernetic law or education. and cybernetic medicine is still in its infancy.

Perhaps there is some methodological impossibility in mixing science with the human factor; the feeling that one cannot unite the heart with the cold calculating machine, in the same way as an artist may feel that the least calculation would throw into confusion the whole of his inspiration.

But we do not reach this point in the techniques of man. They all include—in different proportions—an important calculable part. In medicine this part is so important that, seen from afar, medicine may appear as clear as the technique of an engineer. There is much science in medicine to be written and taught. and this science can, with impunity, find profit in the cybernetic contribution. Compared with law and education, medicine is much more 'cybernetized' in its calculable part. Before letting the human factor speak, laboratory analysis has a word to say.

Education and law are far from having reached this attitude. Instinctively they elude calculation, as would a musician or a painter. Still, law is less defiant of medicine (itself a handler of men, so linked to law on that point) than it is of 'cold' physics. It is through the expedient of medicine that law received the first elements of cybernetic efficiency. Two examples are well known: (1) Law is often led to solve questions relating to health. Formerly these questions were tinged with morals and humanity. Nowadays, the legislator has lost ground to medical techniques (as many people do, who see medicine from the outside, the legislator believes it to be still more scientific, unerring and able to calculate than it really is). The law-giver goes on signing texts referring to infectious diseases or inoculations, but the text is already established before he sees it; the calculations are made by the physician. Would one dare to put to the vote in Parliament medical precepts that are scientifically established? (2) It was a physician who, in 1876, claimed that a criminal was not an ordinary offender but a sick man. Many things have changed since Lombroso's great work. But the whole of criminology still remains, that is to say, the affirmation that a criminal must be nursed and not judged. Here, penal law (at least for what concerns blood, sex and juvenile crimes, etc.) dwindles a little each year; the physician's science taking the place of juridical methods.

To what extent would the physician be ready to do to himself the service done to law? Nothing seems to be against it on scientific grounds, and so long as the human factor holds the decision in the last resort.

Yet things are not quite as simple as they seem. The cybernetic spirit goes towards destroying all human factors. Cybernetics are an alarming partner, and the physician may have the feeling he is losing something in this game. The limits between cold and scientific calculation and the human factor are nowhere distinct, and development in calculation may displace them, by 'de-humanizing' both medical work and the sick man, and even the idea we have of man.

But will the physician really run a risk? It would perhaps be to exaggerate the present power of cybernetics and, above all, minimize the confidence the physician has in the human being. Debate with the cybernetician will sometimes show the human factor as a sham mystery; but if we wanted to approach with love and inspiration what depends on calculation, if it were really a question of sham mystery, here would be a gain in truthfulness and efficiency. The medical aim is human in itself. What does it matter to save a man with a little more or a little less calculation? In our present ignorance, the physician will never find enough in all his heart and in all his calculations; and it is always the human factor which will have the last word.

In truth, this contact with the inhuman and the insensible widens still more the medical horizon.

To consider an organ as a finalized apparatus, to accept the replacement of this organ by a more efficient artificial machine, involves new problems and questions. One sacrifices or modifies a machine to save the life of the man who uses it. One sacrifices a hand, a kidney, an artery, a small part of cornea, to save what? If medicine is a proof of love, to whom does this proof apply[3]?

Just as Socrates, son of Phenarete the midwife, practised the art of 'delivering' the minds, so this fight with the cybernetic angel is in itself maieutic.

The physician must be led, as so many others, to ponder over man. Let us hope he will make his thoughts known.

ORIGIN OF PETROLEUM AND THE COMPOSITION OF THE LUNAR MARIA

By Dr. A. T. WILSON

Victoria University of Wellington, Wellington, New Zealand

ADOPTING a cold accretionary hypothesis for the origin of the solar system[1], it is proposed that the primitive material from which the Earth and Moon were formed contained a small percentage of high molecular weight hydrocarbon, as do some of the meteorites falling on the Earth at the present time (carbonaceous chondrites). During the agglomeration of this material it would have been heated, by release of gravitational energy and by radioactive heating. As the temperature approached 400° C the hydrocarbon would have undergone thermal cracking. The products of this reaction would flow and be distilled to the surface regions of the planet (or Moon). It is suggested that the maria on the surface of the Moon are the residue of this material after the lighter hydrocarbons have evaporated from the exposed surfaces (that is, vacuum-reduced crude oil or asphalt). It is proposed that on Earth this material is petroleum and that it has moved around through porous strata picking up from sedimentary deposits, by solvent extraction, small quantities of biogenic materials. I consider that Nagy, Meinschein and Hennessy[2] have recently carried out a crucial test of the theory by producing a 'petroleum-like' product by the destructive distillation of a portion of the Orgueil meteorite.

Of the meteorites which have fallen, and been recorded, 3·6 per cent are carbonaceous chondrites[3] containing a few per cent (1–5) of carbon[4]. Of the carbonaceous chondrites which have been investigated some of the carbon, perhaps half, occurs as high molecular weight hydrocarbon[2,5–7]. To take a very conservative estimate let us assume that the Earth and Moon were made from material the composition of which was similar to that of the average of all meteorites found. That is to say, that this original material was at least 0·01 per cent hydrocarbon. This does not seem an unreasonable assumption when the cosmic abundance of carbon and hydrogen is considered (2·7 and 2·94 × 10^4 times that of silicon respectively)[8]. The mass of the Earth is 6×10^{24} kg and 0·01 per cent of this is 6×10^{17} tons. If this hydrocarbon were cracked to liquid hydrocarbons with a 10 per cent efficiency, 6×10^{16} tons would be produced, sufficient to cover the Earth to a depth of 40 metres. Such a source is adequate to provide all the petroleum deposits of the Earth. By similar reasoning, such a source would be adequate to provide all the material in the lunar marias.

Petroleum contains large quantities of hydrocarbon in a straight-chain configuration, so a basic assumption of the foregoing proposal is that straight-chain hydrocarbon can be produced by a non-biological mechanism. It is interesting to speculate on the mechanism by which hydrocarbon in a straight-chain configuration could be synthesized in free space. Fig. 1 illustrates how such a material might be produced, via a free radical mechanism, from methyl radicals. The methyl radicals themselves could be produced from solar photons on methane. Such a reaction might be expected to favour addition to the 'end' groups to produce straight-chain hydrocarbon. Small particles of inorganic material would become coated with a layer of high molecular weight hydrocarbon. This has been found by Mueller, who found that some of the silicate of the Cold Bokkeveldt meteorite was insoluble in hydrogen fluoride[5]. High molecular weight hydrocarbon has been produced on surfaces by electrical discharges in a methane–ammonia atmosphere by Wilson[9].

Undoubtedly some of the minor constituents of some petroleums are of biological origin; but it is suggested that petroleum is largely of the origin described here 'contaminated' to a greater or lesser

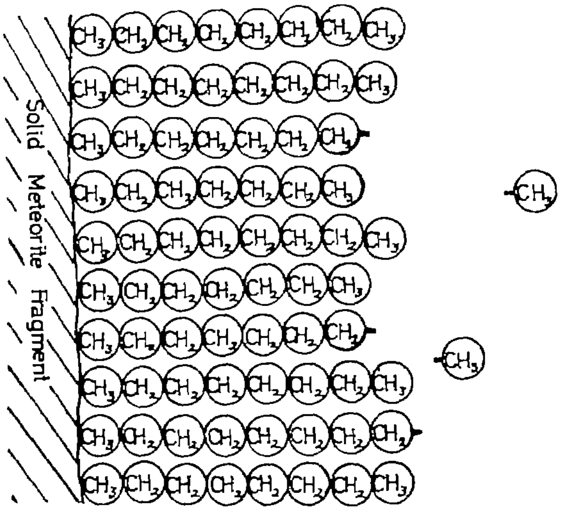

Fig. 1. Proposed mechanism for synthesis of hydrocarbon in a straight-chain configuration

extent by oil-soluble material extracted during its migration through sedimentary deposits.

It is difficult to obtain conclusive evidence to distinguish between a biogenic or the non-biogenic theory of the origin of petroleum. The extra-terrestrial hypothesis suggested here would imply that petroleum could occur on the Moon, whereas a biogenic theory would predict that it would not (unless, of course, life has also 'flourished' on the Moon). It might be expected that some of the liquid products produced by the thermal cracking of this 'cosmic hydrocarbon' would flow to the surface and form great lakes of petroleum. The surface layers of these lakes would lose their volatile constituents and form a skin of vacuum-reduced crude oil or asphalt. The surface of this skin, in turn, would be converted to petroleum coke under the influence of photons and corpuscular irradiation from the Sun.

The maria on the Moon have puzzled observers for many years. Could they be bigger versions of the asphalt lake in Trinidad ? They are extremely smooth and are very dark in colour (albedo = 10 per cent). They have the general appearance of a liquid flow. It has been suggested that they are lava flows; but they have no characteristic terminal faces, and there are objections to any volcanism in the normal sense on the Moon[10]. The temperature properties of their surface are consistent with that of petroleum coke. Radar measurements indicate that the surface is smooth down to a few inches[11]. One might expect debris from meteorite impacts to be lying on the surface of the maria. If the maria were asphalt lakes it would explain the lack of debris since the large fragments would slowly sink into the asphalt. Only rock dust can be supported as, for example, in the case of the ray systems associated with Tycho and Copernicus. It would also explain why the 'seaward' walls of the craters on the edges of the maria disappear—for example, Mare Crisium and Mare Humorum, and the 'seaward' wall of the Imbrium crater. On the foregoing model the 'seaward' wall would have been composed of fragments of asphalt and would have flowed slowly back into place, whereas the 'landward' wall consists of rock debris sitting on a solid bottom. One can see craters in the maria in stages of slumping back; some, for example, in Mare Cirisium, are in an advanced stage and form a lacy network of 'ghosts'. Some of the craters in the maria seem to be filling up—perhaps by asphalt percolating through the rock rubble walls. Areas of no craters (Maria Imbrium and Serenitatis) can be explained by the lake being so deep that asphalt only is displaced in meteor impacts or that any crater wall thrown up from the bottom does not break the surface. Some indication can be gained of the depth of these asphalt lakes from the presence or absence of craters. For example, that part of Mare Imbrium in the vicinity of Archimedes is not nearly as deep as Sinus Iridum. There is evidence that the asphalt is moving slowly, or has moved in the past. For example, some of the craters, such as Ross, seem to be distorted. Some of the craters seem to have been filled to a breach in the wall, for example, Julius Caesar and Posidonius. Some of the asphalt may have come from the impacting bodies themselves. One might imagine a large body of similar composition to the Orgueil meteorite crashing into the Moon. The heat of impact would be expected to crack thermally some of the hydrocarbons present to produce liquid hydrocarbon products.

The low dielectric constant of hydrocarbon is consistent with the very low radar reflexions from the Moon[12].

Is it perhaps possible that the oxidizing environment in which we live on the Earth has blinded us to the cosmic abundance of hydrocarbon ? Is the asphalt lake in Trinidad a last vestige of 'terrestrial maria' ? As has been shown here, even very small cosmic abundances of hydrocarbon could modify the lunar surface considerably, as has the relatively small cosmic abundance of water modified our 'terrestrial surface'. In any event, we probably have only a few years more to wait before we can observe samples of the lunar maria at first hand. If these should prove to be vacuum-reduced crude oil, it will force a major revision in the present-day accepted ideas on the origin of petroleum.

Note added in proof. Since the preparation of the manuscript of the above article a paper by A. Giraud[13] has come to my attention. Giraud has critically reviewed the literature on the exploration of the Moon using electromagnetic radiation. He has calculated the physical properties of the Moon's surface. In Table 1 Giraud's estimates are compared with those postulated in the article here.

Table 1

	Values calculated by Giraud (ref. 13) from electromagnetic radiation received from Moon	Pertinent values (ref. 14) postulated from the hypothesis presented here
Dielectric constant	1–1·5	Petroleum 2·13 Asphalt 2·68
Thermal conductivity (cal sec^{-1} cm^{-1} deg C^{-1})	Of the order of 5×10^{-4} to 10^{-5}	Lampblack 7×10^{-5}
Specific heat	0·1 or 0·2 (cal deg C^{-1} cm^{-3})	Charcoal 0·165 Carbon (amor.) 0·168 (cal deg. C^{-1} gm^{-1}) Density ≐ 2

The specific heat and thermal conductivity measurements would be related to the surface and so should be compared with radiation damaged or cracked petroleum. Dielectric constant measurements would be related to the bulk material and therefore on the proposed hypothesis should be related to asphalt or petroleum.

It has also been concluded from measurements on moonlight that the surface has a vesicular structure with dimensions of granules and interstices in the range 10–300 microns. Such a structure is entirely compatible with petroleum coke[15].

Comment by Prof. G. Mueller*

THE great cosmic abundance of carbon, hydrogen, oxygen and nitrogen leads us to the conclusion that the crust of the Earth must have contained an original non-biogenic carbonaceous phase. What was its composition, and to what extent is it at present preserved, remain open questions.

It should be stressed that all the known deposits of petroleum and related substances, including the asphalt lakes of Trinidad and Venezuela, are within sediments in general and shallow sea deposits in particular. A considerably greater volume of metamorphic and igneous rocks have proved so far to be barren of oil, etc., although the layers of ashes within the older, often folded, volcanics would serve as quite ideal reservoirs covered by the highly impermeable lava-flow traps. On the other hand, the few reliably abiogenic organic mineraloids found in pegmatite veins (tucholites, etc.) have a quite uniquely high oxygen/hydrogen ratio of around 1·0 as against the range of from 0·0 to 0·25 of petroleums and asphalts. It is unlikely that the former substances would yield much of the liquid low oxygen/hydrogen substances on cracking. Indeed, it seems that the main role of life was to differentiate this original high oxygen/hydrogen phase into carbon dioxide and the correspondingly lower oxygen/hydrogen ratio organisms, the partially biochemical decomposition of which yielding still lower oxygen/hydrogen products.

It appears more likely, therefore, that our petroleums would be essentially distillates, etc., of biogenic substances, which in turn picked up small quantities of abiogenic residues.

It appears from our scanty experience that the most probably abiogenic organic substances from the meteorites are also high oxygen/hydrogen complexes, which yield on distillation relatively little hydrocarbons per carbon, and mostly organic acids on extraction. It seems, therefore, that the supposed parent asteroid of the meteorites contained a similar essentially 'acid' carbonaceous phase, as are our terrestrial tucholites. It would be unlikely that such types of substances could freely flow and form the extensive maria. However, it should be stressed that our knowledge of the terrestrial and extra-terrestrial abiogenic carbonaceous phases is based on too few specimens or up-to-date investigations. Ultimately, only the actual exploration of the lunar surface could give us the reply as to the validity of the most interesting observations and their interpretation given by Dr. A. T. Wilson.

STABILITY OF VIRUSES ON *DISCOVERER* FLIGHTS *XXIX* AND *XXX*

By S. S. KALTER, A. HELLMAN, G. T. DAYE, jun., and H. W. JORDAN

Virology Section, Microbiology-Cellular Biology Branch, School of Aerospace Medicine,
Aerospace Medical Division, Brooks Air Force Base, Texas

THE imminence of space travel suggests the need for an increased effort in determining effects of physical and physiological stresses on host–parasite interrelationships. Synthesis of known and speculative conditions encountered during space exploration and the possible influence of infectious disease processes have recently been reviewed[1]. Included among those stress factors are: radiation, hypoxia, temperature, endocrine, nutrition, weightlessness and various combinations. It was of interest, therefore, to ascertain whether or not viruses could be safely orbited and returned to the laboratory, prior to any attempt at experimentally simulating these conditions. The purpose of this report is to give results demonstrating the successful flight and recovery of two animal viruses.

The viruses included in this work were laboratory stock strains of influenza (*PR* 8) and *ECHO* 1. These viruses were selected because of their known inability to produce disease in man or laboratory animals. Furthermore, they differ in their response to deleterious conditions from an unstable virus (influenza) to a relatively stable virus (*ECHO* 1). Influenza stock virus was obtained by inoculation of 9-day-old chick embryos and *ECHO* 1 stock virus from monolayers of monkey kidney cells. Both viruses were collected at the time of maximal replication. Each virus was pooled, lightly centrifuged, and sealed in glass ampoules which were maintained at −70° C. Titrations at various intervals were performed for EID_{50} and $TCID_{50}$ using standard laboratory procedures[2].

A number of successful *Discoverer* flights containing biopacks have been reported[3,4]. Briefly, these biopacks are small air-tight metal canisters, which ride 'piggy-back' on the *Discoverer* rockets. The various biological specimens are tightly fitted into different compartments of the biopacks at the laboratory prior to shipment. In addition to these viruses, other biological specimens included: various tissue and organ cultures, bacteria, algae, insect larvæ, serum and radiation dosimeters.

In general, flights *XXIX* and *XXX* are similar regarding their flight profiles. Table 1 lists an approximation of these data indicating the essential information on both flights. It is obvious, however, that these flights are not critical tests of space conditions inasmuch as the van Allen belt was not

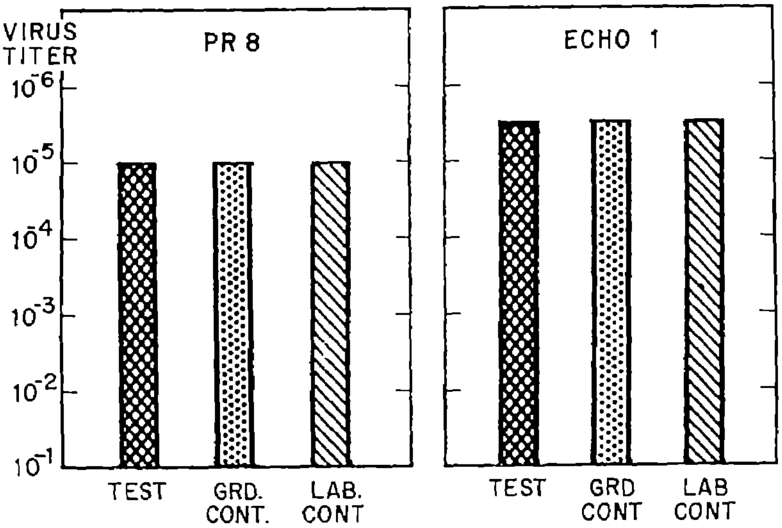

Fig. 1. Effect of *Discoverer XXIX* flight on influenza (*PR 8*) and *ECHO 1* viruses

penetrated nor were detectable radiation effects from any other source readily apparent.

On return to the laboratory, the specimens were frozen (−20° C) and afterwards titrated. Simultaneous tests were performed on the laboratory controls (original virus preparations maintained in the laboratory at −20° C), ground controls (specimens packed similarly as the test but kept at ambient ground-temperatures at the launch site), and the test material. The results of flight *XXIX*, which were identical to flight *XXX*, are shown in Fig. 1.

Table 1. *Discoverer XXIX* and *XXX* Profiles

	Flight	
	XXIX	*XXX*
Launch date	Aug. 30, 1961	Sept. 12, 1961
Recovery	Sept. 3, 1961	Sept. 15, 1961
Site of recovery	Air catch	From sea
Apogee	303·68 N.M.	312 50 N.M.
Perigee	81·49 N.M.	125·00 N.M.
Inclination	82 02°	82·70°
Time of orbit	91·55 min	92·41 min
No. of orbits	33	33
Max. acceleration	9 0*g*	8·0*g*
Duration	450 sec	450 sec
Temperature in capsule	?	16°–37 5° C

It may be noted that excellent agreement was obtained between test and controls with both viruses. Hæmagglutination tests with influenza virus were also performed without any apparent detectable alterations in titre.

The significance of these experiments is the fact that the viruses did withstand the rigours of space flight. Thus vibration, temperature fluctuations, alteration in *g* forces, weightlessness, etc., as produced by these flight conditions do not alter the stability of the virus utilized. Since virus function is not altered, maintenance of functional structure apparently is not impaired by zero gravity. The maintenance of virus structure tends to indicate that gravitational forces as encountered do not contribute appreciably to the stability of intermolecular binding at least for the virus under consideration. Unfortunately no radiation stresses sufficient to alter the virus particle were encountered. However, it is recognized that large radiation dosages are necessary before any effect on the virus particle can be detected by present techniques[5]. Additional investigations are obviously necessary, primarily in the laboratory, to determine the effect of combined stresses on viruses. Furthermore, the ability of these virus suspensions to survive these flights gives impetus to the need for expanding studies on problems associated with the role of viruses as a public health hazard in future space-travel.

ANIMALS OF WESTERN SZECHUAN

By HUNG-SHOU PEN

Kunming Institute of Zoology, Academia Sinica, China

A FIVE-MONTH survey of the animal life in the highlands of western Szechuan Province in south-west China has recently been made.

Traversed by high north–south mountain ranges, western Szechuan has snow-covered peaks as well as deep river gorges; the slopes between are often heavily forested. The Minya Konka, the tallest peak in this region, is 7,700 metres high. While high up on the mountains are glaciers and tundra, in the valleys below the climatic conditions match those of the warm Yangtse Delta. Despite its rich wild life, western Szechuan was visited by few Chinese naturalists in the past.

A preliminary estimate shows that more than one-fourth of the known species of mammals of China and one-third of her known birds are located in western Szechuan. Their species cover a wide range known in the arctic, temperate and tropical zones of the world. The region produces excellent furs and feathers. Tibetan otter furs are generally regarded as the best in China; not until our visit did I realize that the western Szechuan type is equal to the best of the Tibetan species.

Western Szechuan abounds in spotted, black, snow and clouded leopards; reddish golden, grey golden and marbled tiger cats; and lynxes. Their furs are usually very fine, soft and beautiful. Other animals of great economic value are the highland red foxes, silver weasels, beach martens and Himalayan marmots.

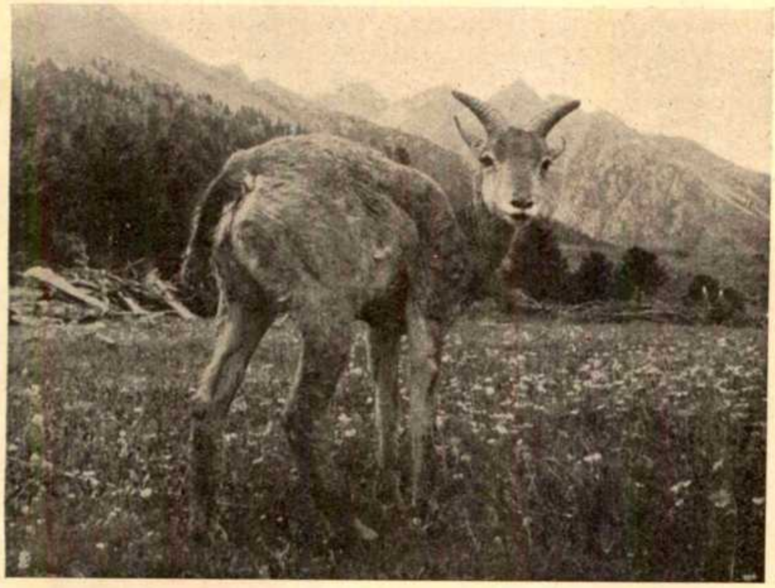

Fig. 1. A blue sheep of Minya Konka

The highlands are the home of a great variety of pheasants, including the golden, Tibetan eared, blood, Stone's, Reeve's, Lady Amherst's, and Chinese moonals and Temminck's tragopans. Their brilliant tail feathers are much sought after as decorations for women's hats and theatrical costumes.

Deer are plentiful around Patang, a county on the western border of the area. They inhabit the barren rocky zone at an altitude of 3,000 metres in the mountains, in the lower grassland and bush, in the forest and down the valley of the Chinsha River at an elevation of 2,000 metres. The alpine grassland abounds in Tibetan gazelles the size of domesticated sheep. In Shichu, in the westernmost part of the region, we found the Asiatic wild asses in herds of hundreds. Beneath the snow-line of Minya Konka the blue sheep ran in flocks of 30–80 (Fig. 1).

Western Szechuan is China's major producer of antlers and musk, both of which are important ingredients in Chinese medicine, while the latter is also used in the perfume industry. Among the deer found in this region were sambars, white-lipped deer and white stags. The two types of musk deer known in western Szechuan are the common musk deer and the Chinese musk deer. Under the skin of the abdomen of the male is the musk gland. The prized secretion of this gland is extracted, often at the expense of the animal's life. The recent success in domesticating the animal in Markang in the northern part of western Szechuan preserves the animal, and steps up the output of musk, for the secretion increases with the animal's age.

Of all the big-game areas in western Szechuan the Yunwu Mountain and the Hsinlu Sea (Fig. 2) are the most outstanding.

A V-shaped mountain range extending some 10 km, the Yunwu Mountain, affords asylum for many of the rarest animals and birds in the world, namely, giant pandas, lesser pandas, golden monkeys, takins, serows, sambars, tufted deer, Reeve's muntjacs, gorals, musk deer, Temminck's tragopans, blood pheasants, Stone's pheasants and Lady Amherst's pheasants. Guided by the local hunters, we traced the giant panda's earthern cave by the tree where the animal passed the winter. In summer, however, it moved to sunken ground covered with moss and grass, as was shown by spoor and droppings. We also identified the pond and the ground where the musk deer, takins and sambars watered.

Hsinlu Sea is a highland lake in the midst of the mountains in western Szechuan (Fig. 2). Around the lake the ruddy sheldrakes and Tibetan eared pheasants breed in profusion, while the shore is dotted with a multitude of caves of otters and Himalayan marmots. The surrounding mountains cover a wide range of faunal elements known in north, south and west China, as shown by the presence of blue sheep, sambars, white stags, spotted leopards, grizzly bears, snow leopards, stump-tailed macaques, serows, gorals, Chinese musk deer and common musk deer.

The first reports of the mammals of western Szechuan by Europeans date from 1869, when Père Armand David, a French missionary, travelled to Paohsing (Muping) County and made an extraordinary collection. The region has since been world famous as a treasure house for mammals and birds.

One of the factors contributing to the rich and remarkable fauna is the region's varied topographical conditions, ranging from the margin of the basin at an elevation of no more than 1,000 m to the 7,700-m high mountain ranges. The north–south running mountain chains set a barrier against the westerly winds, and, by condensing moisture from these air

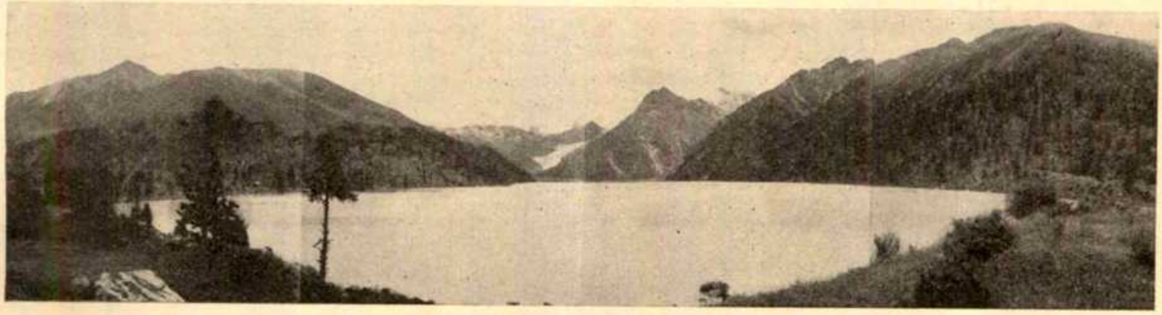

Fig. 2. The Hsinlu Sea of western Szechuan

currents, produce plentiful rainfall, with its consequent forest growth. Along the Chinsha, Yalung and Tatu Rivers are rich warm valleys. The wide range of climatic and geographical conditions makes it favourable as habitation for a great variety of species.

Another factor is the region's geological age. The north–south ranges of western Szechuan are believed to have been established during the last stage of the Pleistocene period, which makes them older than the Himalayas, with which they are contiguous. The mountains seem to have afforded asylum for many primitive types of mammals, including the giant panda, the lesser panda, the golden monkey, the Szechuan jumping mouse and the common Chinese zokor.

The third factor is that the region lies at a latitude where the Palæarctic and the Oriental of the world's zoogeographical regions meet, with the north–south mountain ranges serving as a kind of corridor for the mammals of the two regions. Contact of the north–south ranges with the east–west Himalayas and Kunlun allows a certain interchange or extension of range for some of the faunal elements.

OBITUARIES

Dr. S. T. Ma

THE death occurred in Sydney on January 27, 1962, of Dr. Shih Tsun Ma, senior lecturer in theoretical physics in the University of Sydney.

Dr. Ma was born in Peiping, China, on June 29, 1913. He attended the National University of Peking, first as a student and then on the staff, during 1929–37, obtaining his B.Sc. degree in 1935. From 1937 until 1941 he was a postgraduate student of Queens' College, Cambridge, obtaining his Ph.D. degree in 1941. During this period he worked under and was deeply influenced by Prof. P. A. M. Dirac.

He was then appointed professor in the physics department of his old University, the National University of Peking, and held this position during 1941–45. During this period two of his students were C. N. Yang and T. D. Lee, destined themselves to become distinguished theoretical physicists. In 1945, Dr. Ma left China to become a member of the School of Mathematics, the Institute for Advanced Study, Princeton, where he stayed for two years; he spent the succeeding two years (1947–49) as a scholar in the School of Theoretical Physics, Dublin Institute for Advanced Studies, and the next two years again (1949–51) as a post-doctorate Fellow in the Institute for Nuclear Studies, University of Chicago. During this time he married Mrs. Helen Lin, secretary to Prof. Enrico Fermi. In 1951 he took up a post-doctorate fellowship with the National Research Council of Canada, Ottawa. Finally, in 1953, he joined the Theoretical Physics Department of the School of Physics, University of Sydney, as a lecturer, to be soon promoted to senior lecturer, which position he held until his death at the age of forty-eight years. His stay of almost eight years in the University of Sydney, broken only by a sabbatical study leave in 1960 and spent at the University of Cambridge, was his longest stay in any one place in the Western world.

Dr. Ma's first scientific article, "Variational Wave Functions of Doubly Excited States of Helium", was published, in collaboration with T. Y. Wu, in the *Journal of the Chinese Chemical Society* in 1936. After several such publications in Chinese journals his first article in a Western journal was "Photo-magnetic Disintegration and Magnetic Moment of the Deuteron in the Meson Theory", published in the *Proceedings of the Cambridge Philosophical Society*, 1940. During the ensuing years his thirty-five scientific papers found global distribution in the world's scientific journals; most of these were devoted to subjects in quantum electro-dynamics or meson field theory.

Staff and students alike in Sydney knew Dr. Ma not only as a research leader but also as a man devoted to his work and who prepared and delivered his lectures with meticulous care and a thoroughly sympathetic comprehension of student problems. By his unobtrusive manner and quiet sense of humour he endeared himself to all with whom he came in contact. Dr. Ma's life was obviously influenced by the teachings of Confucius and the ancient Chinese love of learning and devotion to duty. The rigid rules—self-imposed—to which he forced himself to subscribe included the belief that a day is wasted when something is not added to one's store of knowledge. His sole ambition was to contribute to man's scientific knowledge and understanding; it is thus fitting that his contributions to physics should form the monument to Dr. Shih Tsun Ma.

He is survived by his widow and stepson Kenney.

S. T. BUTLER

Prof. Gabriel Bertrand

PROF. G. BERTRAND, who was approaching the age of a hundred, passed away at Paris on June 20, 1962. He was a professor of biochemistry in the Pasteur Institute, Paris, from 1908. There he worked extremely systematically and regularly for sixty years.

During the First World War, I followed his lectures and it was known at that time that Prof. Bertrand advised the French War Office to introduce gas warfare by the application of chlorine. The Germans took possession of his Laboratory during the Second World War, when Prof. Bertrand continued his researches.

He was an extremely gentle and kind man. He created a large School of Biochemistry. He was a versatile research worker and a pioneer in several lines of investigations. This is indicated in the Bertrand Medal, when the following lines occur:

"Venin and vaccination and anti-venin, cellulose and wood, sugars, Sorbose bacteria, lac, laccase, oxydases, diastases and co-diastases, manganese and infinitely small amounts of catalytic chemical fertilizers (trace elements), biocatalysts, chloropicrin, destruction of parasites, etc. . . ."

Prof. Bertrand by his research work established that plant growth and health do not depend only on carbon, nitrogen, oxygen, hydrogen, soda, phosphorus, potash, lime and sulphur, but also on a host of other elements like manganese, iron, copper, zinc, cobalt, boron, iodine; even rubidium and cæsium are present in the plant ash.

He was deeply interested in the history and philosophy of science and attended many congresses. He was a great believer, like Pasteur, Metchnikoff, Roux, Duclaux and others, in the progress of humanity and maintenance of world peace through the experimental method of science. His research work was of great practical value in agriculture and medicine.

Bertrand was a member of the French Academies of Sciences, Agriculture and Medicine.

His only son, Dr. Didier Bertrand, who also is a well-known medical man, is following in the footsteps of his father and pursuing investigations on trace and oligo elements in the Pasteur Institute of Paris.

N. R. Dhar

NEWS and VIEWS

Colour Chemistry and Dyeing at Leeds :
Prof. W. Bradley

The premature retirement of Prof. William Bradley from the chair of colour chemistry and dyeing at the University of Leeds in September 1961, owing to ill-health, was a severe loss to his department. An exceptionally gifted lecturer, he was able to impart to many of his students his own enthusiasm for research, and during the thirteen years (1948–61) in which he occupied the chair, he succeeded—aided by the generosity of industry—in building up a research school that was very large in proportion to the size of his department. Prof. Bradley's name will always be associated with the chemistry of anthraquinonoid vat dyes, a subject on which he is the leading authority. Since 1951 a stream of highly important papers on this subject has appeared in the *Journal of the Chemical Society* under his name and the names of his research students. In particular, he has been interested in the mechanism of formation of vat dyes, a hitherto almost neglected topic. Other fields which he has explored include the chemistry of heterocyclic bases and their metal derivatives, the oxidation of leuco-esters of vat dyes, and azo coupling in non-aqueous media. He has also contributed to the theory of dyeing through his study of the adsorption of mandelic acid (an optically active compound) by wool. He gave every encouragement to his staff to undertake research and was always generous in the allocation of funds and research students. Another notable feature of this period was the introduction into the undergraduate course of lectures and laboratory work on pigments, thus filling a serious gap. It is some consolation to know that Prof. Bradley's health is now much improved, and all those connected with the department, in particular his colleagues and his former students, hope that Prof. and Mrs. Bradley will enjoy many years of happiness in their new home in Paignton, Devon.

Mr. I. D. Rattee

Mr. I. D. Rattee, who is to succeed Prof. Bradley to the chair of colour chemistry and dyeing at Leeds, was educated at the Imperial College of Science and Technology, where he graduated with honours in chemistry in 1945. He is an associate of the Royal College of Science, and in 1960 was awarded the Gold Medal of the Society of Dyers and Colourists. Following graduation, Mr. Rattee was appointed technical officer in the Dyehouse Department of Imperial Chemical Industries, Ltd. (Dyestuffs Division). From 1946 until 1950, he carried on the work initiated by the late Dr. F. Townend on the level dyeing properties of acid and chrome dyes on wool and the relation between these properties and constitution. In 1951, Mr. Rattee departed from the normal lines of wool dyeing research and began work on the use of dyes capable of reacting with the fibre substrate in wool dyeing. He made extensive investigations of the mechanism and chemistry of dye–fibre reactions and examined a class of reactive dyes, containing 2 : 4-dichloro and 2-chloro-4-amino triazin-6-yl groups because of their particular properties for reactivity towards cellulose. This work resulted in the discovery of the reactions which led to the introduction of the Procion dyes in 1956 and the subsequent appearance of an entirely new dyestuff class. Since that time, his work has been almost exclusively devoted to the study of reactive dyes for cellulosic fibres, with particular reference to the development of novel reactive systems, novel techniques of application, and also examination of the fundamentals underlying the behaviour of this type of dye. Mr. Rattee has lectured at the Manchester College of Science and Technology.

The Third Fritz London Award :
Prof. J. Bardeen

Prof. John Bardeen, professor of electrical engineering and physics at the University of Illinois and 1956 Nobel Laureate in physics, has been awarded the third Fritz London Award for distinguished research in low-temperature physics. In collaboration with Prof. Leon M. Cooper, now of Brown University on Rhode Island, and Prof. J. R. Schrieffer, of the University of Illinois, Prof. Bardeen developed the first successful microscopic theory of superconductivity, which is the characteristic loss of all electrical resistance by some metals at extremely low temperatures. In 1957 they published the now well-known Bardeen–Cooper–Schrieffer theory of superconductivity, which has played an outstanding part in the clarification of one of the principal problems of solid-state physics. Prof. Bardeen graduated from the University of Wisconsin, received his doctoral degree from Princeton University in 1936 and an appointment as Junior Fellow from Harvard University. He was with Bell Telephone Laboratories from 1945 until 1951, where he carried out research with Walter H. Brattain and William Shockley on semiconductors, in the course of which they discovered the transistor effect. For this achievement they received the 1956 Nobel Prize in physics. Prof. Bardeen joined the faculty of the University of Illinois in 1951.

The Fritz London Award, established in 1957 and awarded at two-year intervals, is named after the first scientist to elucidate the nature of superconductivity. He also made significant theoretical contributions towards an explanation of superfluidity in liquid helium, the state, unique to this liquid, in which normal viscosity disappears and the liquid 'climbs' the side of its container. The Awards, accompanied by an honorarium of 1,000 dollars, have been sponsored by the ADL Foundation, of Arthur D. Little, Inc., Mass. The first two recipients were Dr. Nicholas Kurti of the University of Oxford (1957) and Lev Davydovich Landau of the Academy of Soviet Sciences (1959).

Reorganization of the Atomic Physics Division at the National Bureau of Standards, Washington

DR. KARL G. KESSLER has been appointed chief of the Atomic Physics Division of the National Bureau of Standards, U.S. Department of Commerce, and Dr. William C. Martin, Dr. Robert P. Madden, Dr. Harold Boyne and Dr. Wolfgang L. Wiese have been named to head reorganized sections of the Division. Dr. Kessler will direct a programme of basic research on wave-length standards, spectroscopy, solid-state physics, interactions of the free-electron, atomic constants, and laboratory astrophysics. He succeeds Dr. L. M. Branscomb, who has joined the National Bureau of Standards–University of Colorado Joint Institute for Laboratory Astrophysics at Boulder, Colorado. Dr. Martin will succeed Dr. Kessler as chief of the Spectroscopy Section. A Far-Ultra-violet Physics Section, headed by Dr. Madden, has been formed to develop radiation standards in the far-ultra-violet spectral region and instrumentation for the investigation of this region. The Section will also investigate the effect of far-ultra-violet radiation on the properties of materials and conduct basic research on the physical phenomena which involve quantitative measurement of far-ultra-violet radiation. Dr. Wiese will be in charge of the new Plasma Spectroscopy Section. This Section will make experimental and theoretical determinations of atomic transition probabilities and lifetimes of excited atomic states, prepare bibliographies on atomic transition probabilities, and tabulate the available numerical data. In addition, spectroscopic techniques for the diagnostics of dense plasmas will be studied and refined, and the shape and shift of spectral lines will be investigated. The Atomic Physics Section will now be headed by Dr. Boyne. He replaces Dr. S. J. Smith, who has also joined the Joint Institute for Laboratory Astrophysics. No changes have been made in the remaining sections. Dr. E. K. Plyler will continue to be in charge of the Infra-red Spectroscopy Section, Dr. H. P. R. Frederikse heads the Solid State Physics Section, and Dr. J. A. Simpson heads the Electron Physics Section.

New Research Laboratory for Reactor Centrum Nederland at Petten

THE firm of Bredero's Bouwbedrijf Nederland is to build a general laboratory on the Reactor Centrum Nederland site at Petten in collaboration with the Engineering and Architect Bureau. The building and furnishing of this laboratory, shortly to be started, will involve about fl. 2·5 million. The building is of modern design and use has been made of the most recent developments in this field. The laboratory will give facilities to about 140 research workers and will consist of two large wings in which the Physical Department will be housed. Further room has been reserved for members of the management and some administrative groups. The general laboratory will be built in the western cup in the dunes of the Reactor Centrum Nederland site at Petten, next to the Fermi building, which is now ready. When finished, a central shop and storehouse building, a lecture theatre and a library will be built. At present, work on the building of a laboratory for highly radioactive materials is in progress. This building will be ready for use by the beginning of 1963. In the spring of this year a temporary building for general services (technical services with drawing-office and administrative departments) was finished. It is expected that, by the end of 1963, 430 research workers will be housed in the various buildings at Petten. At the moment, 385 persons are employed there.

Space Science at the University of Rochester

A CENTER for Space Sciences is to be established at the University of Rochester. The Center will serve as a focus for the interdisciplinary research activities of the many University departments active in space studies and will prepare graduate students for research and teaching careers in the space sciences. The director will be Dr. Wallace O. Fenn, senior professor of physiology at the University. The new unit will be one of the first multi-disciplinary space centres established at a university. Among the academic units which will participate in its activities are physics, engineering, optics, chemistry, biology, psychology, geology, physiology, and radiation biology. The Center is expected to facilitate the work at present being carried out in separate departments and also will encourage new experiments related to space exploration. One of its primary purposes will be to train future space scientists, and initial projects will include a series of seminars for faculty, students, and area industrial scientists working in various phases of space science. An orientation course in space science for graduate students also is being organized. Dr. Fenn has been associated with the University of Rochester School of Medicine and Dentistry as professor of physiology since 1924, and was head of the Physiology Department until 1959. He is well known for his contributions to respiration physiology.

The Scientific Documentation Centre, Ltd., Halbeath, Dunfermline

A NEW research association, the Scientific Documentation Centre, Ltd., is now in operation at Halbeath, Dunfermline. The present organization is continuing the activities of the Scientific Documentation Centre, set up there in 1960. The new unit is carrying out research into the means of improving access to scientific information and is assembling collections of scientific data and operates information services from these, which will be available to research organizations throughout Great Britain and abroad The constitution of the Centre is modelled on those of existing research associations and the Centre functions as a non-profit making company. The Council, which has been formed to control the unit first met in August of this year. The chairman is Prof. P. T. Landsberg, of University College, Cardiff and the members of the Council are Mr. C. E. Kendall Dr. D. M. McIntosh, Mr. J. R. McNally, Mr. M. C Pottinger, Mr. J. F. M. Scholes, and Dr. D. W. A Sharp.

The first service project undertaken by the Centre the *Spectra Index*, is now growing rapidly, and som 3,500 spectra or sets of numerical spectral data—including spectra of several hundred inorganic compounds—are held. All types of spectra are collected but effort is primarily directed to the collection o infra-red and ultra-violet data. Plans to collec nuclear magnetic resonance and related types o spectra will be implemented shortly. Experimental spectra services are being offered, and searches by compound identity and structure will be accepted; spectra can be purchased from those held by the Centre. The Centre also has a substantial collection of specialized data relating to the methods of storage and retrieval of information, and in particular to the use of electronic and photo-electric methods. Documentation advisory services are now being offered, partly on the basis of this. The publications of the Institute for Scientific Information and the Chemical Abstracts Service can be obtained through the Centre. Application for membership of the Centre is open to organizations and individuals requiring research information (annual subscriptions are £15 for an organization, £3 for individuals). Subscribing members receive substantial reductions in the charge for services. A publication, *Spectra Index*, listing the broad types of compound the spectra of which have been copied, is issued to members several times a year.

Studland Heath National Nature Reserve, Dorset

Studland Heath, which covers the more southerly of the twin promontories almost barring access from Poole Harbour in Dorset to the English Channel, has been declared a National Nature Reserve by the Nature Conservancy. It is an intricate complex of sand-dunes, freshwater lagoons, lowland heaths and bog covering the seaward fringes of the ridges formed by the sandy Bagshot Beds. Its flora and fauna were the subject of a comprehensive biological survey begun in the 'twenties by Capt. C. Diver, the first director-general of the Nature Conservancy (1949–52). The establishment of this Heath as a National Nature Reserve was officially recommended in the *Report of the Wild Life Conservation Special Committee* (Cmd. 7122, July. London: H.M.S.O., 1947). This emphasized the overlapping at Studland of distributional limits of many south-eastern and south-western species and the educational importance of the 'diagrammatic' zoning of maritime, sub-maritime, dune, heath, marsh, freshwater and woodland vegetation types on acid soils. The Conservancy has leased 429 acres, including the freshwater lagoon called the Little Sea and the representative range of both old and younger sand-dunes except for their seaward frontage within a hundred feet of high-water mark. These, with the low-lying woodlands and marshes extending back to the Ferry Road and one detached bog with heathland to the west of the toll-gate, have been declared as the Studland Heath National Nature Reserve.

Translocation of Game Animals in the Kruger National Park

During recent years a number of scientists, game wardens and trappers have conducted investigations on the immobilization of game by means of a dart-syringe containing paralysing or hypnotic drugs. This is a completely new field of research for the veterinarian, the zoologist and the nature conservator, but its value and importance in nature conservation cannot be over-estimated. It enables the scientist to study the migration of game by marking suitable individuals, facilitates the transport and re-introduction of game into areas where they have become extinct, and makes possible veterinary research without the shooting of game. The Department of Nature Conservation of the National Parks Board of Trustees, Republic of South Africa, has recently initiated research on the immobilization and transportation of game. J. W. Van Niekerk, State veterinarian, and Dr. U. de V. Pienaar, biologist, Skukuza, Kruger National Park, have described some of the results (*Journal for Scientific Research in the National Parks of the Republic of South Africa*, No. 5; 1962). Work was commenced on the blue wildebeest (*Gorgon taurinus taurinus* Burxhell) for the object of migratory studies, the impala (*Aepyceros melampus melampus* Lichtenstein) for physiological observations and diagnostic purposes in diseases, such as foot and mouth disease, and in the case of the hippopotamus (*Hippopotamus amphibius capensis* Linnaeus) for re-introduction to the Eastern Cape.

The Atomic Gardening Society

The Atomic Gardening Society is a "scientific, educational, non-profit-making body" which carries out research on plant breeding using irradiated and chemically treated seeds and plants. Samples of seeds are exchanged between members and any variations which occur are recorded and, if possible, developed. The Society publishes a *Digest*, the latest issue of which contains information about chemical mutagens, radioactive irradiation of grain in the U.S.S.R., irradiation of African violets and peas and lettuce treated in Sweden (3, No. 3; June 1962. Pp. 10. The Atomic Gardening Society. Dr. Thomas Gray, "Winnipeg", Winchelsea, Sussex, 1962).

Sir Henry Tizard

Mr. R. W. Clark, of 10 Campden Street, Kensington, London, W.8, writes to the Editor of *Nature*, stating that he is preparing a biography of the late Sir Henry Tizard (with approval of Sir Henry's family). The Tizard papers, to which he is being granted full access for use in the biography, are very considerable. He would, nevertheless, be grateful to hear from any readers who have reminiscences of Sir Henry's life and work, or who possess letters from him.

Announcements

Mr. Walter Binaghi has been re-elected president of the Council of the International Civil Aviation Organization. The Council is the permanent governing body of the Organization, and is elected by the Assembly for a three-year term. Mr. Binaghi was first elected to the presidency of the Council in 1957.

A conference on "Hydraulics and Fluid Mechanics", sponsored by the Faculty of Engineering, University of Western Australia, is to be held in Perth during December 6–13. Further information can be obtained from the Conference Convener, School of Engineering, University of Western Australia, Nedlands, Western Australia.

An exhibition of plastics and machinery, entitled "Centenary of Plastics 1862–1962" and arranged by the North-Eastern Section of the Plastics Institute, will be held at the Rutherford College of Technology, Newcastle upon Tyne, during November 6–10. Further information can be obtained from Mr. P. C. Oliver, 45 Worcester Way, Newcastle upon Tyne 1.

A symposium on "Recent Developments in Iron and Steel-making with Special Reference to Indian Conditions" has been jointly arranged by the Indian Institute of Metals, the National Metallurgical Laboratory (India) and the Iron and Steel Institute (U.K.) during February 4–8, 1963. Further information can be obtained from the Director, National Metallurgical Laboratory, Jamshedpur-7, India.

THE NUFFIELD FOUNDATION

SCHOLARSHIPS IN FOOD SCIENCE

THE Nuffield Foundation has become increasingly interested in the field of food science, with special regard to what it sees as a need for more fundamental research and for more people capable of carrying it out (see also p. 1 of this issue). Simplification and labour saving in the preparation and storage of food involves the greater use of food additives and of various processing techniques, and toxic risks may therefore be increasing. The Foundation, guided on these matters by an advisory committee, is aware of considerable gaps in knowledge in this field; limitation of knowledge of the pathology of test animals appears to be a basic deficiency.

While there appears to be a reasonably satisfactory position in the training and supply of food scientists and technologists to carry out standard procedures, the numbers available for fundamental research are entirely inadequate; in particular, among pathologists and pharmacologists with toxicological interests and experience, and among food scientists with postgraduate qualifications who have adequate training and experience in more than one discipline.

The Foundation is anxious to encourage entry into this field by means of a scholarship scheme. It is hoped that these awards may attract science and medical graduates who might not otherwise contemplate a career in food science research. Career prospects in this branch of science are now good; official and public interest in the field, as with academic and industrial interest, is quickening and the demand for highly trained scientists will continue to grow. The recent setting up of the British Industrial Biological Research Association is a practical expression and measure of this quickening interest.

At a later date the Foundation may be able to give further support to this developing career structure by the offer to selected post-doctoral candidates of senior research fellowships.

With the aim of helping to advance research into the more important problems of food science the Nuffield Foundation is prepared to offer annually up to five research scholarships for science graduates and up to three research scholarships for medically qualified graduates.

The awards, which may be held for periods of up to four years if necessary, are intended to provide suitable experience and knowledge to qualify graduates in science and medicine for subsequent research in food science.

Science graduates will be able to receive, as necessary, a year of more or less formal training in selected subjects and to study for the Ph.D. degree in the field of food science and toxicology. The value of the awards will be between £650 and £900 per annum if taxable, or the equivalent tax-free, according to age, qualifications, and experience, and subject within these limits to annual increments of £50. The value will be supplemented by the amount of fees, an allowance of £50 per annum if married, and a further £50 per annum for each child up to the first two. Additional expenses likely to arise in connexion with a scholar's research programme, other than normal bench fees, which will be automatically covered, will be sympathetically discussed on an *ad hoc* basis.

Graduates in human or veterinary medicine will be able to receive, as necessary, a year of more or less formal training in selected subjects and to study for a Ph.D. degree in pathology or toxicology or other higher degree approved by the Foundation. The value of the awards will be between £800 and £1,200 per annum if taxable, or the equivalent tax-free, supplemented and subject to the same conditions as for science graduates.

The scholarships will be open to men or women preferably under the age of thirty-five, who hold a science, medical or veterinary degree of a United Kingdom or other Commonwealth university, who are of high merit and whose ability and inclinations fit them for a career in food science research. A candidate for a scholarship must be recommended by an appropriate professor or other authority of the university where the candidate graduated, and of the university or other institution at which the candidate would wish to receive training.

Scholarships will not normally be tenable for longer than four years.

If a scholar is allowed to spend part of his period of study abroad or to travel in Britain in connexion with his work, travelling expenses will be paid.

A scholar may not hold any other award concurrently with his scholarship, nor undertake other work, paid or unpaid, without the permission of the Nuffield Foundation.

Both the programme of work and training, and the institute at which it is to be carried out, must be approved by the Foundation.

Should the Foundation at any time find that a scholar neglects or has neglected the obligations of his appointment, it shall have power immediately to terminate his scholarship.

Selection for scholarships is to be made twice a year. Forms of application are obtainable from the Director of the Nuffield Foundation, Nuffield Lodge, Regent's Park, London, N.W.1.

SPECIAL CERAMICS

THE development of new technologies and the increasing tendency to seek greater operating efficiencies at higher temperatures create a rapidly growing demand for special ceramics, to withstand conditions too severe for metals or traditional ceramics. Nuclear engineering and the supply of power at microwave frequencies are two fields where progress in design and construction now requires the development of new high-performance materials. The engineer looks to the ceramist to provide these materials. The impetus of this demand is reflected in the growth of the small group working on special ceramics at the British Ceramic Research Association of the ceramic industries into a major division of the

Association in but a few years. The terms of reference of this group are wide, covering the preparation and testing of new materials, mostly non-oxides, for specialized electrical, nuclear and high-temperature applications, including rocket nozzles, and the assessment of existing materials as potential valve components; its research is carried out in close co-operation with various Service departments and industrial concerns. The first symposium on special ceramics, held by the British Ceramic Research Association in 1959, received enthusiastic support, and the proceedings were edited by P. Popper and published by Heywood and Company in 1960 under the title *Special Ceramics*. Its success led to the holding of a second symposium, under the same heading, at the Association's Laboratories during July 11–13, 1962. This was attended by 170 delegates from seven countries, representing universities, Government departments, research associations and industrial concerns. The twenty-five papers contributed were grouped into sessions under the headings: preparation and properties of non-oxides; oxides; pyrolytics; measurement; techniques; applications of ceramics.

Dr. N. F. Astbury, director of the British Ceramic Research Association, opened the symposium and welcomed the delegates.

The research described in the opening paper, read by Dr. E. D. Lynch (Argonne National Laboratory) on behalf of his colleagues J. H. Handwerk, P. D. Shalek and G. D. White, was stimulated by the need for new nuclear fuels to give greater reactor operating efficiencies. Refractory uranium compounds other than oxides were being investigated, with emphasis on uranium monosulphide and uranium monocarbide, their preparation and their properties. The closely related paper by M. C. Regan and J. W. Isaacs (Atomic Energy Research Establishment, Harwell), read by H. J. Hedger, described the effect of various additions of uranium monocarbide, uranium dicarbide, uranium metal and plutonium monocarbide on the reaction-sintering behaviour of uranium/carbon mixtures and on the density of the monocarbide produced.

The synthesis, purification and hot pressing of silicon hexaboride and silicon tetraboride and the assessment of their mechanical, thermal and electrical properties and resistance to oxidation were described by R. S. Feigelson and Prof. W. D. Kingery (Massachusetts Institute of Technology). Both borides were reported as semiconductors with high resistance to oxidation. Aluminium nitride is a highly refractory non-oxide which, like silicon nitride, is chemically inert and should prove a useful material, especially for applications in contact with molten aluminium. The preparation of pure aluminium nitride by levitating aluminium in a radio-frequency field in an atmosphere of nitrogen was described by Drs. C. F. Cooper, C. M. George and S. W. J. Hopkins (Morganite Research and Development, Ltd.), who also showed that its oxidation was controlled by the rate of diffusion of aluminium ions through the oxide layer. The appearance of profuse whisker growths on aluminium nitride was described by Dr. P. E. Evans (Manchester College of Technology) in the discussion.

The formation of protective coatings on graphite to improve its oxidation and erosion resistance is to-day the subject of considerable study and, in a combined paper, A. E. S. White, Dr. R. F. Deacon, J. Chown and Dr. N. Singer (Morganite Research and Development, Ltd.) described two methods of coating graphite with silicon carbide, composite coatings containing zirconium diboride, and the testing of these in an oxidation furnace, at 2,300° C in a high-temperature flame and in a liquid oxygen/kerosene rocket motor. In the discussion F. C. Carpenter (S. Smith and Sons, Ltd.) pointed out the usefulness of a fluidized bed technique in building up coatings on sharp edges of articles. Beryllium oxide is another material of interest for nuclear power applications. The sintering characteristics of various beryllium oxide powders, the effects of particle size and impurities, and the conditions that must be satisfied if high density is to be achieved were detailed by A. W. Hey and Dr. D. T. Livey (Atomic Energy Research Establishment, Harwell).

Pyrolytic decomposition is sometimes the only means of producing a pure, dense material in bulk form, since many refractories do not sinter and can be hot-pressed only by the incorporation of additives. It is often used to form dense coatings on a heated substrate: good, adherent coatings require that the thermal expansion coefficients of coating and substrate should match closely. The session on pyrolytics opened with a description by P. Popper (British Ceramic Research Association) of the preparation of silicon carbide and the nitrides of aluminium, boron, phosphorus and silicon by pyrolysis, from gases or vapours containing the constituent elements in the correct proportion. Pyrolytic carbon was discussed in two contributions. The first, by Dr. K. W. Carley-Macauly and M. Mackenzie (Atomic Energy Research Establishment, Harwell), indicated the development of new types of very low permeability carbons and graphite for high-temperature gas-cooled nuclear reactors, by impregnation of a porous bed in which a large temperature-gradient is maintained. The second, by Drs. J. Harvey, D. Clark and J. N. Eastabrook (Royal Aircraft Establishment, Farnborough), considered how the structure and crystallographic orientation of pyrolytic carbon varied with the temperature of deposition, surface roughness and graphitization. There was a considerable discussion of the mechanism of growth of the observed cones in the layers.

The electrical properties of rutile, with particular reference to its anisotropy and breakdown, were discussed by M. G. Harwood (Mullard, Ltd.), who showed that the conductivity along the c-axis could increase without affecting that in the perpendicular direction and that small filamentary regions carrying high current were present. The frictional properties and deformation of refractory borides and carbides at high temperature were discussed by C. A. Brookes (University of Cambridge), with reference to the adhesion theory of friction. Slip was observed along (111) planes of titanium carbide single crystals and the mechanism of deformation of polycrystals was considered.

In the session on measurement and techniques, measurements of the thermal conductivity of pyrolytic graphite at temperatures up to 2,100° C were reported by W. Johnson and W. Watt (Royal Aircraft Establishment, Farnborough). The accurate measurement of thermal conductivity is always very tedious, and great interest was shown in the report by Dr. R. W. Powell and R. P. Tye (National Physical Laboratory) of measurements made very rapidly with a new, direct-reading form of thermal comparator and agreeing well with other methods. An automatic dilatometer for the measurement of thermal expansion up to 1,500° C in controlled atmospheres was

R330

described by K. N. Preece (Morganite Research and Development, Ltd.).

Dr. S. Scholz (Philips, Aachen) discussed the rate of densification of refractories during hot-pressing and the effect on this of activating impurities, such as iron in tantalum carbide. A. W. Moore and Dr. D. A. Young (Imperial College of Science and Technology, London) showed how the anisotropy of electrical and thermal conductivity of well-oriented graphite had been utilized in the design of susceptors for induction heating, in the attainment of temperatures up to 3,400° C. The radial pressure produced in a powder during its compaction in a die and its relation to compacted density were discussed by W. M. Long (Atomic Weapons Research Establishment, Aldermaston). The application of the electron microscope to ceramics, in the study of grain structure and surface texture, in the identification of crystalline fibres and fine particles by electron diffraction, and in following reactions, including the nitridation of silicon, was considered by Dr. S. N. Ruddlesden (British Ceramic Research Association).

The final session of the symposium was devoted to the applications of ceramics. Dr. A. J. Moulson and P. Popper (British Ceramic Research Association) first outlined the physical properties required of a ceramic for use as valve envelopes and windows, and the methods of measuring these properties in order to assess the suitability of a ceramic for valve applications. J. Free and Dr. D. Walsh (University of Oxford) described new uses of ceramics at ultra-high frequencies (cm and mm wave-lengths). Ceramics of low dielectric loss could be used as reflectors of microwave power, with the reflexion exceeding that of a pure silver surface, and experiments using titania were discussed. With non-linear dielectric materials it is theoretically possible to generate microwave power. The succeeding paper, by Dr. K. H. Kreuchen (Electrical and Musical Industries, Ltd.), considered the special ceramic problems arising with the growing use of very-high-power valves in the transmitters of television stations, radar systems and particle accelerators, including the need for low surface resistivity to avoid charge build-up from the plasma, new shapes for wave-guide windows to achieve broad-band performance, and secondary emission qualities. T. D. Davidson and J. Watkins (Morganite Research and Development, Ltd.) described the preparation of high-power microwave absorbing loads from silicon carbide and the variation of its semiconducting properties by the addition of silicon.

The theoretical and practical advantages of using ceramics in microwave tubes for particle accelerators and amplifiers, and the impressive performance obtained on a laboratory scale, were demonstrated by J. Free (University of Oxford), who stressed the need for the commercial development of new materials and predicted that accelerators using ceramics would eventually outclass those of conventional type, on a cost basis, offering higher efficiencies and higher operating frequencies. In the magneto-hydrodynamic generation of electricity, materials are subjected to unusually severe conditions at temperatures above 2,000° C. Dr. E. G. Wolff (Central Electricity Research Laboratories, Leatherhead) described the preparation and testing of some refractory borides, carbides, oxides and silicides as possible electrode and duct materials for such generators. The session closed with an illustration by W. F. Gibbons (Ferranti, Ltd.) of the ceramic-to-metal sealing technique and its application to problems in the field of nuclear engineering.

At the conclusion of the symposium the visitors toured the laboratories of the British Ceramic Research Association. The proceedings of the symposium will be published by the Academic Press in due course.

S. N. RUDDLESDEN

SCIENTIFIC RESEARCH IN BELGIUM

THE annual report of the Institute for the Encouragement of Scientific Research in Industry and Agriculture, Brussels, for 1961 records 65 grants totalling some 244·5 million francs distributed to some 229 investigators and 423 technicians*. A new grant of 21·5 million francs went to the Committee for Establishing the Soil and Vegetation Map of Belgium for its systematic study of the pedological character of the soil and completion of the pedological map of the kingdom. The Committee for the Study of the Solid State received a grant of 11·69 million francs towards research in progress in Prof. Dekeyser's laboratory at the University of Ghent on semi-conductors, in the Laboratory of the Electrical Construction Works at Charleroi on the study of magnetic steel sheets, and in Prof. Brasseur's laboratory at the Gevaert factory on the improvement of photographic supports by perfecting the method of acetylation: a further grant of 2·15 million francs was for continuation of the Committee's work on the welding of resinous materials, 1,787,500 francs for research on the preparation of hard magnetic materials, and one of 9 million francs for continuation of research on the mechanism of photographic processes and for work on new photographic processes. The Carbochemical Society of Tertre received a grant of 3·9 million francs for continuation of work on textile colours, and the Gevaert Photo Products Society 7·225 million francs for the study of photographic dyes and processes of colour photography.

A grant of 10·19 million francs went to the Committee on the Application of Isotopic Methods in Agronomic Research for research on the utilization of radioisotopes, and one of 9 million francs to the Research Centre of Gorsem for continuation of work on diseases and insect pests of various cultivated fruits with the view of a system of control, and also of research on the maturation and conservation of fruit and the influence of insecticides and fungicides on the physiology of the vegetables to which they are applied. The Technical and Scientific Centre of the Belgian Glass Industry received some 8·5 million francs for its research on the properties and homogeneity of glass, the mechanism of action of abrasives and on enamels for glass, while a grant of 7,386,000 francs to the National Centre for Metallurgical Research was for analytical research by spectrochemical and X-ray methods, physical metallurgy investigations, fundamental research by microcinematography on the mechanism of fracture, and various applied investigations; further grants of 2.795,000 francs and 5,050,000 francs were for continuation of research on the mechanical properties of steel and on methods of utilization of steel, and one of 6.500,000 francs for continuation of research on cobalt.

---

* Institut pour l'Encouragement de la Recherche Scientifique dans l'Industrie et l'Agriculture, Bruxelles. Rapport Annuel-Exercice 1961. Pp. 266. (Bruxelles: Institut pour l'Encouragement de la Recherche Scientifique dans l'Industrie et l'Agriculture, 1962.)

The Committee for the Study of the Problem of Nitrogen received a grant of 6,660,000 francs for research on nitrogenous fertilizers in Belgium soils, including investigations on nitrification and absorption of nitrogen by vegetables A grant of 6,027,000 francs to the Centre for Biological Chemistry and Soil Colloids was for investigations on the transformation of organic matter in the soil, mineral colloids of the soil and on the cationic and organic manuring of soils. The Centre for Research into Forestry Biology received 5,590,000 francs for pedological, entomological and genetic research devoted towards improving the exploitation of forests and their conservation by natural regeneration. The Centre for Scientific and Technical Research on the Conservation of Vegetables received a grant of 5,222,000 francs for scientific and technical research on the cultivation of vegetables for conserving and on the conditions of conservation; 4,165,000 francs went to the Centre for Research on Agriculture for work on the mineral alimentation of vegetables, 3,700,000 francs to the Centre for Research on Vegetable Hormones, 3,210,000 francs to the Centre for Research on Parasitic Diseases of Domestic Animals, 2,835,000 francs to the Centre for the Study of the Forest Soils of Ardennes and Gaume; 5,470,000 francs to the Scientific and Technical Research Centre of the Explosives Industry and 5,174,079 francs to that of the Belgian Textiles Industry. Other grants included 3,350,000 francs to Dr. C. Janssen's Research Laboratory for research on the synthesis of ring systems with 3 or 4 atoms of carbon; 2,456,450 francs to the Laboratory of the Varnish, Paints, Printing Inks and Art Colours Industry and 2,835,000 francs to the Centre for the Study of Ornamental Plants for work on plant diseases and the cultivation of chrysanthemums and cyclamens. Other grants included 2,162,000 francs to the Technical and Scientific Centre of the Woodworking and Related Industries; 1,980,000 francs to the Pedological Service of Belgium for researches on magnesium and on minor elements in vegetables; 1,840,000 francs to the Foundation for Potato Research; 1,770,000 francs to the Committee for the Study of Apiculture; 1,525,000 francs to the Committee for Strawberry Research; 1,160,000 francs to the Committee for the Scientific and Technical Study of Lactation; and 1,086,000 francs to the Belgian Institute for High Pressures.

THE AUSTRALIAN DEFENCE STANDARDS LABORATORIES

THE function of the Australian Defence Standards Laboratories is outlined in the annual report for the year ended June 30, 1961*. Its main concern is the application of scientific knowledge and research within the fields of chemistry, physics, metallurgy and engineering to problems arising in the design, manufacture, inspection and use of defence material. In addition, as its name implies, it is concerned with standards of measurement and standards of quality. The report deals with the general activities of the establishment and with some of the more important projects and investigations either completed or in progress in the fields of chemistry, metallurgy and physics.

In the Chemistry Division research has continued on the mechanism of the initial film formation on lead alloy anodes in sea-water, and the initial film has been shown to contain lead sulphate and some carbonate, in addition to lead chloride. Infra-red spectroscopy has been used for the study of a series of *bis*-pyridinium oximes. The cæsium bromide prism of the double pass spectrometer was calibrated for the far infra-red and a curve fitted to twenty points by orthogonal polynomial methods. The best fit was given by a cubic expression. The application of the Stokes parameters of electromagnetic radiation to the description of the state of polarization of Raman lines has been considered, and a procedure has been developed for the calculation of the intensity ratios and depolarization factors. The new apparatus of Lench and Martin for low-pressure gas analysis, used in conjunction with improved apparatus for vacuum fusion gas extraction, collection and measurement, has been in constant use during the period under review for the determination of the gas content of chromium metal and chromium alloys by the vacuum fusion method.

During the year, major improvements were made to the control system of the air-conducting plant of the metrology laboratory in the Physics Division to enable temperatures in the Length Standards Room to be maintained at 20° C ± $\frac{1}{4}$° C irrespective of external conditions. Considerable developments in the application of interferometry to measurements of length are reported. A Varian wide-line nuclear magnetic resonance spectrometer with associated electromagnet and power supply has been installed, and is being used to investigate the concentration of the fluoride catalyst in the chromic acid solutions used in the production of chromium. Electron spin resonance has been used to study the defects produced by γ-rays on a commercial polymethyl methacrylate. New values for X- and γ-radiation absorption coefficients have been obtained, and designs for counters for the detection of soft X-rays have been developed and constructed.

The Metallurgy Division has been largely concerned with the evaluation of one of the Australian chromium-based high-temperature alloys processed under quasi-industrial conditions. This includes ductility studies, internal friction measurements and observations of the creep behaviour. Work has continued on cleavage in cast molybdenum of high purity and in wrought chromium. As a contribution to the understanding of the abrasion of metals, the sliding of a metal specimen on silicon carbide abrasive papers has been studied, and it has been found that the majority of abrasive particles make a groove in the surface of the metal, piling up a ridge on either side, but removing little or no metal. An idealized model of the process has been devised and an expression obtained for the rate of removal of material with allowance made for the deterioration in use of the abrasive paper. Using metallographic techniques it has been established conclusively that the damage, produced in the surface layers of slices of germanium for use in semiconductor devices when cut from large single crystals and lapped to size, is due to cracks, and new methods of preparation of the slices which will considerably reduce the extent of the damage are being developed.

MENTAL HEALTH IN THE WORLD

It is difficult to estimate the prevalence of mental illness, but in countries where services for the mentally ill are relatively highly developed, psychiatric cases account for almost half the total number of patients occupying hospital beds. Apart from cases in hospital, too, a considerable proportion of the world's population suffers from minor forms of mental ill-health which do not require hospitalization but may disorganize social relationships and productive capacity. It has been suggested that to provide satisfactory treatment for all cases of psychiatric disorder one psychiatrist is needed for every 20,000 people—a requirement that has so far been met in only a few areas.

The main concern of the World Health Organization in mental health has been to develop knowledge that can be applied in public health administration by its Member States. The reports of its Expert Committee on Mental Health and of its study groups on related subjects, for example, provide a conspectus of international views on policy in this field as they have developed over the past twelve years. Laying special emphasis on preventive work, the Organization has assisted the development of psychiatric services in Member States through seminars, conferences and fellowships and by providing consultants and expert advice. Its educational influence in mental health has been further extended by its publication of a number of authoritative studies—on topics from the architecture of psychiatric hospitals to the epidemiology of mental disorders—by leading international authorities. The World Health Organization has also done much to foster both basic and applied psychiatric research.

A new booklet, which is a reprint of a series of articles that appeared in the *WHO Chronicle* between March and July 1962, surveys those aspects of mental health work with which the World Health Organization has been particularly concerned *. These include: the development of psychiatric services; the mental health tasks of the public health services; problems of prevention and treatment; education, training and research, and programme development. There is also a bibliography of World Health Organization reports and studies on mental health.

WIDESPREAD IONOSPHERIC DISTURBANCES DUE TO NUCLEAR EXPLOSIONS DURING OCTOBER 1961

By PROF. TATSUZO OBAYASHI

Ionosphere Research Laboratory, Kyoto University, Kyoto

A SERIES of Soviet nuclear tests made during October 1961 at Novaya Zemlya reveals the evidence of strong blast waves propagating through the ionosphere over a considerable distance. Two large nuclear tests were carried out at 08h 28m on 23 and at 08h 33m on October 30, 1961, which were probably of 30 and of 50 megatons, respectively. Although the exact situation of the tests at Novaya Zemlya is not known, the detonations were made probably in the troposphere. Some preliminary investigations on the remarkable ionospheric disturbances associated with these explosions have already been reported. At Scandinavian stations, the ionograms showed a sudden heavy disturbance in the *F* region of the ionosphere about half an hour after the detonation[1,2]. A large increase of f_0F_2 and subsequent oscillatory variations with a period of 1½ h were found at Lindau, Germany, being delayed about 2 h[3]. Short-wave radio communications between Europe and Japan (*GBJ*–34, 14·80 Mc/s, and *DGP*–862, 15·86 Mc/s) deteriorated immediately and rather poor conditions lasted several hours[4].

Similar ionospheric disturbances have been known at the high-altitude nuclear explosions over Johnston Island during August 1958. The travelling F_2 disturbance was found which spread several thousand kilometres over the Pacific area[5-7]. Photographs of the explosion taken from Hawaii indicated clearly the existence of an expanding luminous front through the upper atmosphere[8]. Since these disturbances may possibly be due to shock waves spreading out from the explosion, the investigation of the present effect by the world-wide ionosonde network would be of great value. Thus, ionospheric data at about 30 stations in the northern hemisphere have been analysed.

The results for two events on October 23 and 30, the time variations of f_0F_2 at several key stations in Europe and in Asia, and the field-strength record at the route Hamburg–Osaka (15·86 Mc/s) are illustrated in Fig. 1. The great-circle path of the Hamburg–Osaka is deviated about 1,000 km from the shot point. It is shown that an anomalously large increase and subsequent fluctuations of f_0F_2 were observed at all European stations, and smaller effects in Japan. The peak of increased f_0F_2 was delayed progressively from nearer to distant stations. This travelling disturbance was confirmed in India and in South-East Asia. Both

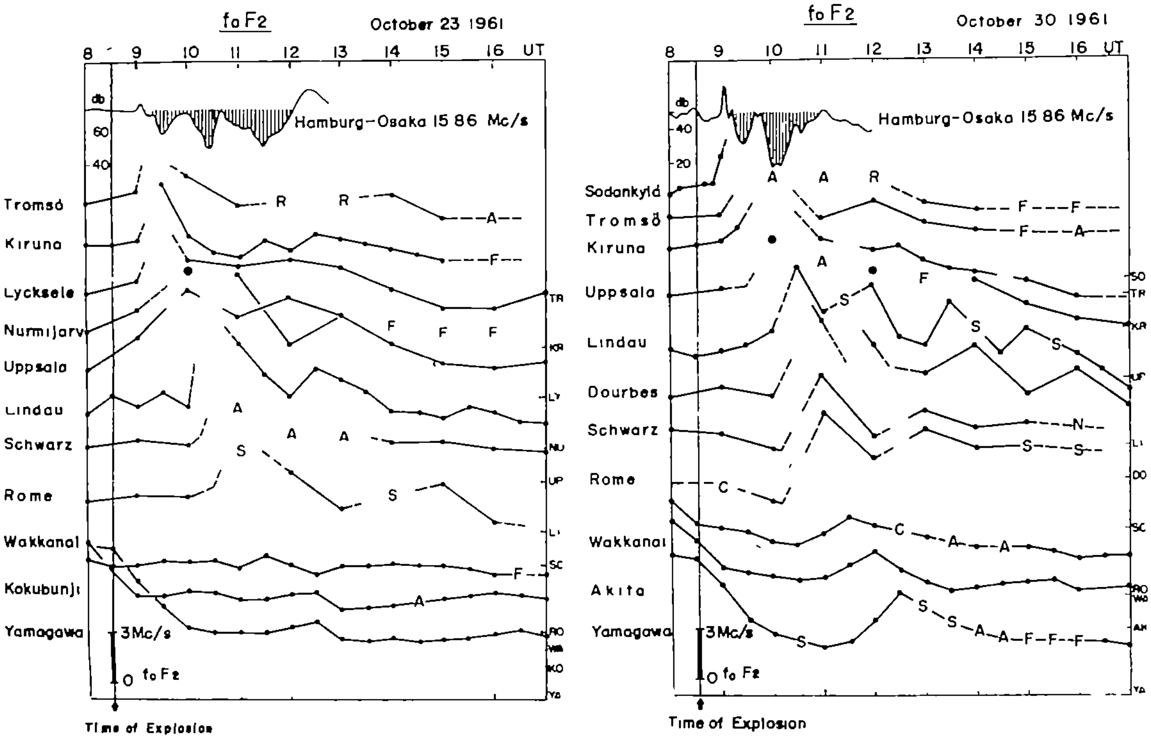

Fig. 1. Time variations of f_0F_2 and the field-strength *DGP*-862 (15 86 Mc/s) during the periods of nuclear explosions on October 23 and 30, 1961

events of October 23 and 30 are quite similar, except a more turbulent condition for the second one.

Travel-time versus distance diagrams of F_2 disturbances are given in Fig. 2. It is evident that the disturbance spread out with nearly a constant speed over several thousands of kilometres. The speed of these travelling disturbances was of 400–500 m/s, significantly faster than the speed of sound in the stratosphere. In spite of such widespread effect over the Eurasian continent, little or no effect was noticed at the North American stations, although their distances are comparable with those of European stations.

On the other hand, it has been reported that the pressure waves were propagated all over the world and were observed by microbarographs[1,2,9,10]. The mean velocity was about 310 m/s with wave-length of the order of 100 km. Round-the-world echoes of the F_2 disturbance were also noticed by Rose, Oksman and Kataja[2] and Dieminger and Kohl[3]. It has been inferred, further, that the travelling disturbance wave would have an excess velocity near the detonation, but be propagated later with nearly constant velocity of 420 m/s. The wave-length is estimated to be about 200–300 km, and hence a dominant period of such a wave would be 10 min or somewhat more.

The nature of such a travelling disturbance wave is a matter of speculation. It appears, however, that the disturbance may have its origin in propagating atmospheric waves controlled by gravitational and compressional forces. The internal atmospheric wave has two types, depending on its wave frequency[11,12]. In the high-frequency range the behaviour is that of an acoustic (sound) wave, while in the very low frequency the gravitational forces introduce a profound anisotropy and essentially it may be called the gravity wave. The characteristic frequencies separating these two domains are known as the Vaisala-Brunt frequency (gravitational stability

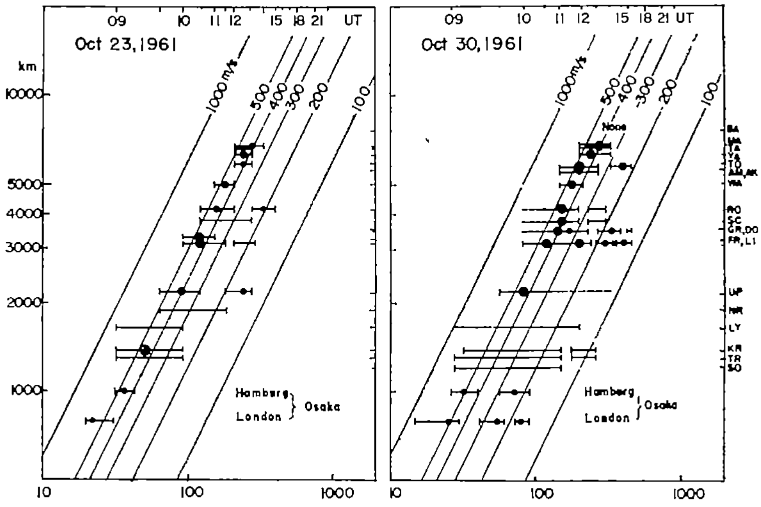

Fig. 2. Travel-time versus distance diagrams of the ionospheric F_2 disturbances for the events on October 23 and 30, 1961. Oblique lines show the travel-time curves for constant speeds

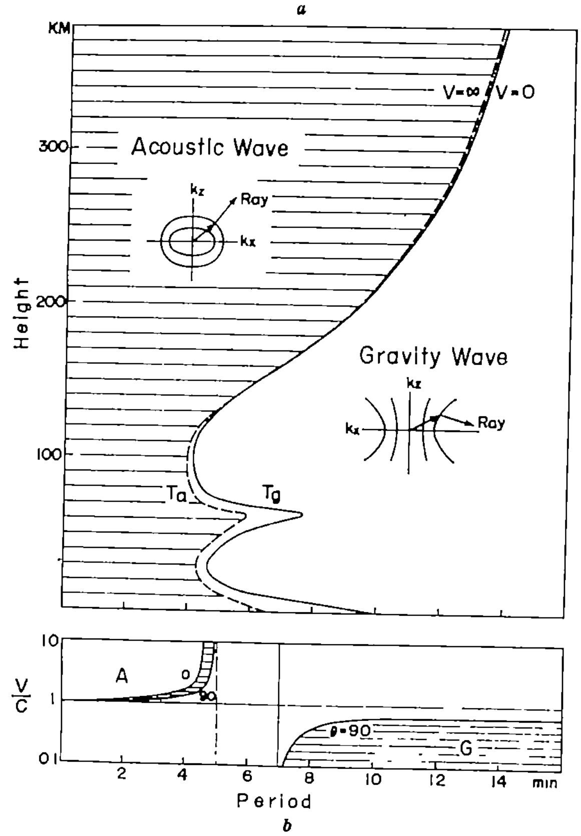

Fig. 3. *a*, Altitude profile of the stability frequencies T_g and T_a in the upper atmosphere; *b*, phase velocity of atmospheric waves at the height of 60 km

frequency) ω_g, and modified (acoustic) stability frequency ω_a. For the atmosphere in hydrostatic equilibrium with density $\rho(z)$ and the speed of sound $c(z)$, they are given[13] by:

$$\omega_g^2 = -g\left(\frac{g}{c^2} + \frac{1}{\rho}\frac{\partial\rho}{\partial z}\right) = \frac{g}{H}\left[\frac{\gamma - 1}{\gamma} + \frac{\partial H}{\partial z}\right]$$

and

$$\omega_a^2 = \left(\frac{c}{2\rho}\frac{\partial\rho}{\partial z}\right)^2 = \frac{\gamma g}{H}\left[1 + \frac{\partial H}{\partial z}\right]^2$$

where g is the gravitational acceleration, γ is the ratio of specific heat and H is the scale height. The phase velocity V of the wave is given:

$$\left(\frac{V}{c}\right)^2 = \frac{1 - Y\sin^2\theta}{1 - X}$$

where $X = (\omega_a/\omega)^2$, $Y = (\omega_g/\omega)^2$ and θ is the angle between the gravity field and the wave normal.

Two characteristic periods ($T = 2\pi/\omega$) in the upper atmosphere and horizontal velocity of the wave at approximately 60 km height are depicted in Fig. 3. The propagation-surfaces at two domains are also shown. They indicate that the acoustic waves propagate more or less isotropically, while the gravity waves. exhibit a strong anisotropy, tending to propagate in the horizontal direction.

Since the wave produced by the explosion at high atmosphere has the period of 10 min or more, the atmospheric gravity wave must be most conspicuous in the region of the upper atmosphere. The attenuation of waves through the upper atmosphere is due mainly to the air viscosity and the thermal conduction. The linear attenuation loss due to viscous damping is given approximately by $\mu/\rho c(2\pi/\lambda)^2$, where μ/ρ is the kinematic viscosity in which μ is (2–5) × 10^{-3} c.g.s. in the ionospheric region. Then, the attenuation distance should be of the order of 6,400 km at 150 km height ($\rho \simeq 2 \times 10^{-12}$ g/cm^3) for the wave-length of 250 km. Therefore, the wave suffers negligible attenuation below the F region, although the attenuation increases rapidly above this height owing to the exponential decrease of the air density.

On the other hand, it is shown theoretically that the wave tends to increase its amplitude of oscillation with increasing height, in proportion to $\exp(z/2H)$. Then the region of most intense disturbance will be determined by the competing effects of dissipation and the upward growth of wave amplitudes. This would place the largest amplitude of waves in the lower F region. Furthermore, the gravity waves of their period of 10 ~ 15 min are bounded only in the region below 200–300 km, and the phase velocity of wave becomes much slower than the local speed of sound near the upper fringe. This may be that an intense shock wave is inevitably generated in this region, since the speed of the disturbing agent may easily exceed the phase speed of the medium.

It will also be noted that, for the gravity wave of its period well above T_g, the ratio of horizontal and vertical wave-lengths is very large, and the movements of gas particles are followed in the horizontally elongated ellipse. However, in the F_2 region the motion of particles, especially of electrons, is affected profoundly by the existing geomagnetic field. This implies that the atmospheric gases may move with the waves, but electrons can execute their movements only along the field lines.

Taking account of these factors, a somewhat schematic illustration of the wave motions together with the horizontal velocity profile of the gravity waves at some representative periods are shown in Fig. 4. The amplitude of wave grows exponentially with increasing height until the dissipation dominates over this, and a shock wave may develop near the upper fringe. This

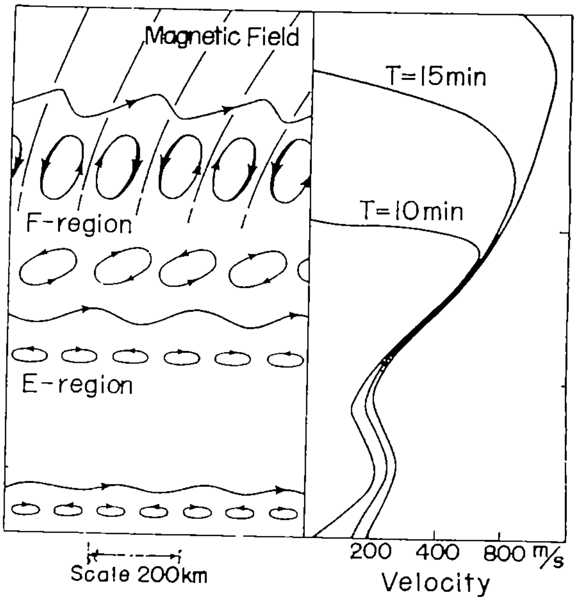

Fig. 4. Pictorial representation of the behaviour of the gravity waves and their speed in the upper atmosphere. Motion of air particles and electrons, and the wave-forms at different altitudes are depicted

may explain why a strong disturbance is observed in the F region but not in the E region. Sharp shock fronts produced by the convergent movement of ionization may attribute specular reflexion of radio waves, and result apparently in the temporal increases of penetration frequency (f_0F_2).

The transportation of the wave energy to very long distances warrants further discussion. As has been pointed out by Hines[12], there must exist a strong ducting of the energy in the lower ionosphere below the thermal incline. The main flow of the energy may propagate quasi-horizontally in the duct, although the duct is admittedly leaky and attributes the disturbance in the F region. Since the viscous dissipation of the wave is negligible at the wave-length of a few hundred kilometres, it would appear that the wave propagates greater distances without excessive attenuation, being reflected at the antipodal point of the explosion. This has been well demonstrated by the observed round-the-world echoes of travelling disturbances[2,3].

AMBIENT XENON: A KEY TO THE HISTORY OF METEORITES

By ROBERT A. FISH*
Lick Observatory, University of California, Mt. Hamilton
AND
GORDON G. GOLES
Departments of Chemistry and Earth Sciences, School of Science and Engineering, University of California, San Diego

THE existence of isotopic anomalies in meteoritic xenon has been firmly established by Reynolds and other investigators[1–6]. Xenon in many meteorites exhibits a 'special' anomaly, in which the isotope xenon-129 is greatly enhanced with respect to terrestrial xenon, as well as smaller 'general' anomalies affecting the remainder of the xenon isotopes. Conflicting explanations of the general anomalies have been offered[7,8], but it does seem clear that the xenon special anomalies are a result of the meteorite parent bodies having formed quickly enough after the last synthesis of iodine-129 to permit an excess of the radiogenic daughter xenon-129 to accumulate in the iodine-bearing minerals. Jeffery and Reynolds[9] have shown that the 'excess' xenon-129 and the iodine in the Abee chondrite are almost certainly located at the same sites, thus supporting the above interpretation. The research initiated by Reynolds has therefore established 'xenon chronometry' as a fundamental tool in studies of the early solar system, because it provides a measure of the interval from iodine synthesis to the cooling of the meteoritic minerals. Since it is not certain which processes contributed to the nucleosynthesis of iodine, one can only derive relative rather than absolute decay intervals.

We believe that Reynolds's data concerning meteoritic xenon carries, in addition, information about the interiors of meteorite parent bodies, information which rivals in importance the xenon chronometry. In discussing these data, we shall suggest an improvement on one unsatisfactory aspect of xenon chronometry—that the special anomalies have been determined by comparison with unsuitable reference standards.

The first characteristic of the interiors of the meteorite parent bodies that we must consider is their isolation from the surrounding primitive solar nebula. In our model, the outer layer of the meteorite parent body represents both a thermal wall and a barrier to gaseous diffusion. The portion of this barrier that lies at temperatures below 300° K would scarcely be less than 1 km in thickness for parent bodies 50 km or more in radius, barring unbelievably large heating-rates much in excess of 0·05 cal/g/yr.[10]. DuFresne and Anders[11] have suggested that the interiors of the parent bodies contained water which would freeze in the barrier layer as on a cold trap, and thereby form a 'wall' of ice. While this barrier might be temporarily ruptured during the evolution of meteorites, any such ruptures would be self-sealing, as DuFresne and Anders have pointed out. Both the existence of such an icy wall and the strong tendency for xenon to be adsorbed at low temperatures would tend to inhibit exchange between the interiors and the surrounding nebula. Thus, there appear to be at least two mechanisms for the isolation of the interiors of meteorite parent bodies. Furthermore, evidence does exist both for such isolation and for mixing within the internal atmospheres. In exploring this evidence, we can show that higher pressures of volatile materials were maintained inside the meteorite parent bodies than outside, and that significant evolutionary changes in the xenon mass spectrum occurred before the meteorites completed their physical and chemical development.

One meteorite of particular importance in this connexion is the Sardis iron. An analysis of a sample of troilite from Sardis indicated that it has an iodine content of 3·6 p.p.m., a factor of 100 greater than that typical of ordinary chondrites[12]. Preliminary measurements by Reynolds, Merrihue and Pepin[13] show that Sardis troilite contains radiogenic xenon-129 accompanied by 'primordial' xenon, with a total xenon content of $4{\cdot}2 \times 10^{-10}$ c.c./g (Table 1). Using data of Jeffery and Reynolds for Abee[14,15], it is possible to estimate the difference between the decay intervals of these two meteorites by assuming only that the ($^{129}I/^{127}I$) ratio was the same for these meteorites at any given time. It is not necessary to postulate a definite value for this ratio, so that one

* Fellow of the Miller Institute for Basic Research in Science, University of California.

Table 1. XENON ANOMALIES IN SARDIS AND ABEE

Sample	δ_M‰ normalized to ^{132}Xe ^{129}Xe	 ^{131}Xe	Total Xe c.c.STP/g
Sardis troilite	318 ± 10	81 ± 5	4·2 × 10^{-10}
Sardis metal	160 ± 25	31 ± 10	2·6 × 10^{-11}
Abee	4400 ± 100	4 ± 16	8 × 10^{-9}

δ_M‰ = 1000 [(^{M}Xe/^{132}Xe)/(^{M}Xe/^{132}Xe)atm—1]

need not rely on specific models of iodine nucleosynthesis. We have used the procedure of Reynolds *et al.* to compute 'excess' xenon-129 (by subtracting the atmospheric xenon spectrum) and find that Abee has the shorter decay interval by about 190 m.y.

The interpretation of this difference requires some caution. The assumption of identical (^{129}I/^{127}I) ratios in the two meteorites is valid in general only if they were derived from a homogeneous nebula, or if they both represent material from the same well-mixed element of an inhomogeneous nebula. Since the general anomalies at xenon-131 differ for the two samples (Table 1), it might be argued that this is not the case. However, even a variation in iodine isotopic composition by a factor of two will only give rise to an error of 16·4 m.y. in this calculation. While our estimate of the difference in these decay intervals may be modified when sufficient data on Sardis troilite become available, it seems likely that the difference is a real one under any interpretative scheme and due to different times required for cooling these meteorites. (In the following sections it will be shown that the 'conventional' model is essentially justified for Abee. For Sardis, however, the proportion of xenon-129 produced by the decay of indigenous iodine-129 is not known. Nevertheless, if one assumes in the extreme case that all xenon-129 in Sardis troilite was produced by decay of indigenous iodine-129, the difference in these two decay intervals would be reduced by no more than 35 m.y.) In Fig. 1 we have given volume-average and central cooling times for meteorite parent bodies of various dimensions containing the complement of long-lived radioactivities which they possessed about 4·5 × 10^9 years ago. The difference in Abee and Sardis decay intervals supports the view that Sardis was once part of the well-insulated core of a parent body of perhaps 100-km radius, while Abee may have evolved in the mantle of a similar object. It is also evident that for asteroidal-sized bodies the volume-average cooling times are comparable to the entire xenon decay intervals characteristic of meteorites. (Goles, Fish and Anders[16] arrived at the same conclusion previously, from a discussion of argon diffusion in stone meteorites.)

Let us now consider whether the observed 'primordial' xenon in these and other meteorites may be considered to be a relic of internal atmospheres of parent bodies, or whether it is a sample of the gases of the solar nebula. Murthy and Patterson[17] have reviewed the lead isotope data now available and have concluded that the primary lead–lead isochron of zero age for meteorites and that for the Earth agree to within a standard deviation of 1·7 per cent. Thus, the date of the primary uranium–lead differentiation for any meteorite and for the Earth may be assumed not to differ by more than 150 m.y., applying a 95 per cent confidence limit. Radiogenic xenon could only have been retained in Abee some time after the uranium–lead differentiation in the materials of that meteorite, which from the argument of Murthy and Patterson can scarcely have occurred as much as 150 m.y. prior to the corresponding differentiation for the Earth. Thus it is evident that the retention of radiogenic xenon in Sardis troilite, and perhaps in Abee as well, was an event approximately contemporaneous with or possibly later than the formation of the Earth's crust. For Abee, at least, xenon-132 is lost on heating more easily than is xenon-129. Therefore, the retention of 'primordial' xenon probably began later than that of radiogenic indigenous xenon-129, whether one interprets the data with the conventional model or with that to be developed. Although data on Sardis troilite are lacking, exchange of 'primordial' xenon in Sardis with xenon in its environment probably was rapid at high temperatures, so that retention of indigenous xenon-129 and the fixation of its 'primordial' xenon should have occurred nearly simultaneously.

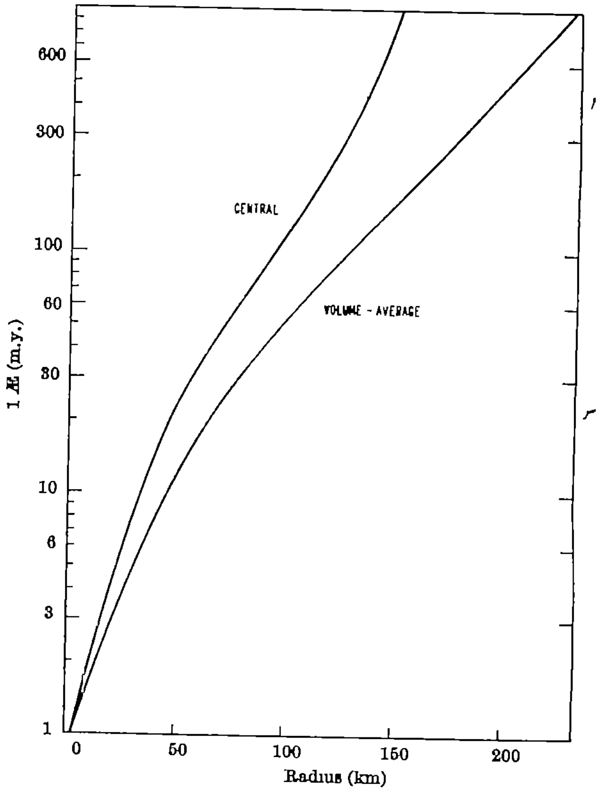

Fig. 1. Cooling times versus radius for meteoritic parent bodies. The times required for central and volume-average temperatures to fall from 700° K to 200° K were computed from the relations given by Allan and Jacobs[20]. The following assumptions were made: (1) the only heat source during cooling was ^{40}K, 1·45 × 10^{-9} deg. y^{-1}; (2) thermal diffusivity $K \equiv 1 \times 10^{-2}$ cm^2 sec^{-1}; (3) the surface temperature was fixed at 100° K by radiation

Suess[18] and Urey[19] have presented compelling evidence that when the Earth was formed, the solar nebula was already grossly depleted in noble gases. It is difficult to believe that Sardis troilite, which cooled at very nearly the same time, obtained its 'primordial gases' from the nebula at a time when the Earth was unable to do so. Instead, it seems much more plausible that Sardis was isolated from the exterior of the parent body and cooled under a substantial partial pressure of highly evolved gases. These gases, absorbed on cooling, were not necessarily identical with the gases that were expelled on first heating the primitive materials of the parent body and so it would be misleading to call them 'primordial', despite their large abundance.

We shall refer to this absorbed gas as 'ambient', to emphasize that it does not necessarily have the same composition as the gases of the primitive nebula. In particular, we suggest that radiogenic xenon-129 (from iodine-129) and xenon-131–136 (from fission of heavy elements) was produced in those regions of the parent body that were at relatively high temperatures and mixed freely with the ambient xenon, so that the isotopic abundance in ambient xenon of xenon-129 and xenon-131–136 increased with time. The progressive enrichment of the ambient gas in xenon-129 is a most significant characteristic of our model, because it is confirmed by a direct experimental check that will be described in the next section. But it should be noted that evolutionary changes in the ambient gas have been anticipated in earlier papers[10,11]. Fish *et al.* propose that the initial state of the parent bodies was that of a cold, small object, perhaps 50–100 km in diameter, containing a large amount of condensed volatiles such as water, CH_4, H_2S, and ammonia. (Subsequent work by Miller[20] has shown that these compounds might have entered the parent bodies in a matrix of gas hydrates). On heating, it is argued, volatile materials in the central regions of these bodies were vaporized and participated in oxidation-reduction reactions. These volatile compounds may have played a part in the extraction of chalcophile elements which was termed the 'sulphur cycle' by Fish *et al.* Physical fractionation of these gases might have occurred during transport within the parent body, their escape to the nebula, and the eventual re-absorption of a surviving portion by the minerals as they cooled. DuFresne and Anders give detailed evidence for the action of water on the minerals of the carbonaceous chondrites and the absorption by the aqueous solutions of sulphur dioxide and carbon dioxide, and show how appreciable pressures of gas—consistent with xenon partial pressures of 10^{-5}–10^{-6} atmospheres—might have been retained in the interiors of the parent bodies during their cooling era.

If one supposes that each meteorite's xenon originated in a single, closed environment in which some degree of gaseous mixing could take place, it becomes possible to monitor the evolutionary stage of the ambient gas, and also to gain new insight into the xenon dating method. We shall use data obtained with the experimental approach utilized by Jeffery and Reynolds[9], although we shall place a different interpretation on the results. Jeffery and Reynolds sought to establish the association of anomalous xenon-129 with meteoritic iodine by means of neutron irradiation of the meteorite, followed by heating experiments. 'Anomalous' xenon-129 in their sense is the xenon-129 in excess over the amount of xenon-129 that corresponds to the terrestrial or carbonaceous chondrite $^{129}Xe/^{132}Xe$ ratio. In the meteorite Abee, an excellent correspondence of the thermal release patterns of pile-produced xenon-128 (which we call xenon-128*) with anomalous xenon-129 was found. In several other meteorites such a correspondence was also apparent but not as convincing.

If we regard the terrestrial $^{129}Xe/^{132}Xe$ ratio as having no special cosmochemical significance, we must find a more general way to separate the total meteoritic xenon-129 into a radiogenic component, xenon-129 (indigenous), associated with iodine-127 and a component associated with the ambient gas. We shall assume that only these two components exist and that the ratio xenon-129 (indigenous)/xenon-128* is independent of temperature in the heating experiments. Xenon-129 (indigenous) is therefore equal to a times xenon-128*, where a is a constant, for each xenon fraction released on heating. Similarly, xenon-129 (ambient) is equal to b times xenon-132 for each fraction, where b is another constant. The total xenon-129 in any fraction is then:

$$^{129}\mathrm{Xe} = a\,^{128}\mathrm{Xe}^* + b\,^{132}\mathrm{Xe} \qquad (1)$$

On normalizing to ^{132}Xe we obtain:

$$\frac{^{129}\mathrm{Xe}}{^{132}\mathrm{Xe}} = a\left(\frac{^{128}\mathrm{Xe}^*}{^{132}\mathrm{Xe}}\right) + b \qquad (2)$$

Note that for three or more fractions, equation (2) should define a straight line if our assumptions are valid. This relation also is of a particularly convenient form, because the intercept b should represent the ratio $^{129}Xe/^{132}Xe$ in the ambient xenon at the time when the meteorite became retentive of xenon, and the slope a is related to the decay interval Δt through the formula:

$$a = \left(\frac{^{129}\mathrm{I}}{^{127}\mathrm{I}}\right)_0 \left(\frac{^{127}\mathrm{I}}{^{128}\mathrm{Xe}^*}\right)_{\mathrm{monitor}} \exp\left(-\Delta t/\tau_{129}\right) \qquad (3)$$

The ratio $(^{127}I/^{128}Xe^*)$ in the monitor (used to calibrate the neutron flux) is a measurable quantity, and $(^{129}I/^{127}I)_0$ signifies the ratio of radioactive to stable iodine at the beginning of the decay interval. It is a quantity that is fixed by the model adopted for iodine synthesis. τ_{129} is the mean lifetime of ^{129}I (23·7 m.y.).

Equation (3) fixes the decay interval Δt uniquely, once $(^{129}I/^{127}I)_0$ is assumed, the monitor activation-level has been measured, and a has been determined by a least squares fit of equation (2) to the irradiation and heating data. Since this technique separates the ambient from the indigenous xenon-129 component, no external normalization is required. Freedom from normalization to a terrestrial xenon mass spectrum or a xenon mass spectrum characteristic of the carbonaceous chondrites is a gain in three respects. First, xenon of both the Earth and the carbonaceous chondrites is only remotely related to 'primæval' xenon, since in one case there is evidence for strong physical fractionation[18], and in the other for advanced chemical evolution[11], probably accompanied by fractionation. Secondly, equation (3) makes it possible to date the carbonaceous chondrites, as cannot be done if they are used as a basis for normalization. Thirdly, even samples showing negative xenon-129 'anomalies' can in principle be dated as they could not under the earlier procedure.

We have described an idealized case. A real meteorite would have required an appreciable time to cool from those temperatures at which exchange with the ambient xenon is rapid for all sites to those temperatures at which exchange is greatly inhibited for all sites. Thus, high-temperature sites (presumably those contributing to the high-temperature xenon fractions of the heating experiments) may contain ambient xenon which is discernibly 'younger' than that of the low-temperature sites. Similarly, the high-temperature sites might be expected to have an anomalously high content of indigenous xenon-129, compared with low-temperature ones. Fortunately, since the measured quantity in question is the $^{129}Xe/^{132}Xe$ ratio in xenon from each group of sites, these two effects tend to cancel. Only if the average $^{132}Xe/^{129}I$ ratio in the source of the ambient xenon had been very different from that in the meteorite during its cooling would any large error be introduced. In real meteorites there is presumably more than one iodine-bearing mineral, which conflicts with the assumption that the ratio ^{129}Xe (indigenous)/^{128}Xe* is independent of temperature in the heating experiments. This problem will not always be unmanageable however, for it may be that a single mineral will contain most of the iodine and other minerals will only introduce a certain degree of scatter in the points. In other cases two minerals may be important, but will release xenon at such different characteristic temperatures that the two sets of data will be essentially independent of one another. In general, the most refractory iodine-bearing mineral may be treated by our procedure if only high-temperature points are considered. As noted here, fission of heavy nuclides adds xenon-132 to the ambient xenon and so might have changed the basis of normalization during cooling. Owing to the probable low abundance of fissionable nuclides, this effect will be assumed to be negligible. Finally, problems of pre-terrestrial diffusion losses, surface iodine contamination, and contamination with adsorbed atmospheric xenon, all lead us to question the suitability of low-temperature data for use in the above relations

There are four stages of investigation that will provide checks on the correctness of the assertions made earlier in this article.

(1) *Applicability of Equation* (2). Do the irradiation and heating experiments (which we shall call for convenience 'correlation runs') give data that lie on a straight line, with a positive non-zero intercept, when ^{129}Xe/^{132}Xe is plotted against ^{128}Xe*/^{132}Xe ? Reynolds *et al.* (private communication) inform us that this is the case, although correlation runs have been made for only a small number of meteorites so far. This provides a check on our assertion that one may decompose the xenon-129 into ambient and indigenous components according to equation (2). Jeffery and Reynolds have kindly permitted us to reproduce a graph that makes use of the co-ordinate system suggested here and the data from their most recent correlation run on the meteorite Abee. It is shown as Fig. 2. All the high-temperature points ($\geqslant$ 900° C) show an excellent linear correlation, suggesting that in Abee we approach the ideal case of rapid cooling (hence a well-defined Δt) and a single dominant refractory iodine mineral. The data also suggest that a second iodine mineral is making some contribution to the points obtained at lower temperatures. The presence of two separate sources is indicated when one recognizes (as did Jeffery and Reynolds[14]) that the ratio ^{128}Xe*/^{132}Xe should reach a maximum at the temperature of maximum release of xenon from any given iodine-bearing mineral. By grouping the points of Fig. 2 into sequences 600°–1,000° and 1,100°–1,500° according to this rule, one observes that the former would yield a linear regression of smaller slope and larger intercept than the latter. The data are only suggestive however, and do not merit a formal computation. The lowest temperature points at 400° and 500° may be influenced by yet another release pattern, although they are those most subject to error due to iodine and atmospheric xenon contamination.

Let us return to considering the high-temperature correlation alone. In the case of Abee, the linear relationship that emerges from this type of plot is not surprising, considering the correlations obtained by Jeffrey and Reynolds[8]. The value of the intercept in Fig. 2 is 0·94 ± 0·16, indicating a ratio of xenon-129 to xenon-132 in the ambient gas at the time that the meteorite cooled that is not distinguishable from the terrestrial ratio of 0·983. Hence, in subtracting the terrestrial ^{129}Xe/^{132}Xe ratio, Jeffrey and Reynolds in effect subtracted the constant b from a set of linear relations of the form $y = ax + b$. In the case of some of the other meteorites, for which Reynolds and co-workers will shortly publish data, the correlations that emerge on using expression (2) were masked to some degree by the former type of analysis, since the ratio of ^{129}Xe/^{132}Xe in the ambient xenon is not always close to the terrestrial ratio.

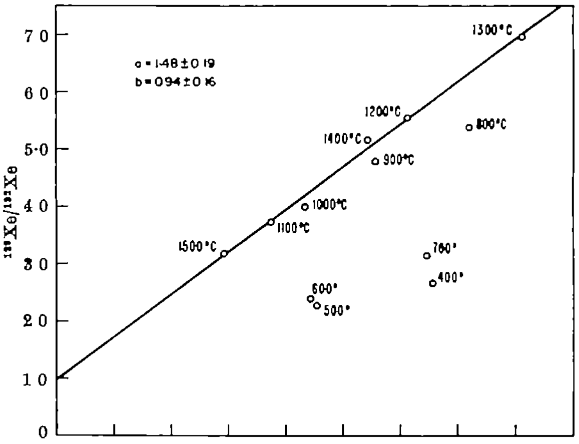

Fig. 2. Correlation of ^{129}Xe/^{132}Xe and ^{128}Xe*/^{132}Xe from Abee according to equation (4). The points for 900°–1,500° C were fitted by linear regression of ^{129}Xe/^{132}Xe on ^{128}Xe*/^{132}Xe

(2) *Evolution and source of ambient xenon.* Do the decay intervals obtained from equation (3) show a positive correlation with the parameter b of equation (2) ? This is necessary if we are to assume that the ambient xenon is a valid indicator of the 'age' of the gas that was reabsorbed in the meteorite on cooling, as expressed in its ^{129}Xe/^{132}Xe ratio. The results of Reynolds *et al.* suggest that this is also the case, although for several meteorites the data are only preliminary. It may eventually be possible to use the composition of the ambient xenon to define decay intervals independently of Δt's obtained from the parameter a.

The variation of b, the ratio of ^{129}Xe/^{132}Xe in the ambient xenon at the time of cooling, appears to be 30–40 per cent (based on 4 meteorites). This is easily seen to be too large a range to be explicable by free decay of iodine-129 in an undifferentiated homogeneous solar nebula. Adopting for the cosmic abundance of iodine-127 the value of 0·2 c.a.u. and for xenon-129 the value 1·05 c.a.u. (1 c.a.u. = 1 atom/10^6 silicon atoms; Suess and Urey[21]), a 40 per cent variation in b from one meteorite to another requires a ratio of ^{129}I/^{127}I at the time of formation of the meteorite with lowest b near 2·0. By way of contrast, three popular models for iodine synthesis yield considerably lower values for the ratio ^{129}I/^{127}I : $2 \times 10^{-4} \exp(-\Delta t''/\tau_{129})$ for solar nebula synthesis[22]; $5 \times 10^{-3} \exp -(\Delta t' + \Delta t'')/\tau_{129}$ for continuous galactic synthesis[23,24]; and $2 \times 10^{-1} \exp -(\Delta t' + \Delta t'')/\tau_{129}$ for a 'mixed' nucleosynthesis with a 10 per cent last-moment contribution[25]. Here $\Delta t'$ refers to the time-interval between the isolation of the solar nebula and the formation of the meteorite parent bodies, and $\Delta t''$ to the interval from formation of the parent bodies to the cooling of the meteoritic minerals with the lowest value of b. Thus, free decay in the undifferentiated solar nebula clearly cannot produce a 40 per cent modification in the ratio $^{129}\mathrm{Xe}/^{132}\mathrm{Xe}$. Such a modification can easily have been achieved in the postulated interior atmospheres however, for even the most xenon-rich meteorites (such as Murray) have iodine/xenon ratios 10^4 times higher than undifferentiated cosmic material.

(3) *Data from separated phases.* While we may rule out evolution of ambient xenon in an undifferentiated nebula, the question of whether the observed variation in b could have arisen during the dispersal of the solar nebula still remains to be studied. Fortunately, it is possible to recognize evolution in the closed environment of an interior atmosphere as opposed to that in the open environment of the solar nebula by the following test: Do correlation runs on separated phases of the same meteorite (which presumably cooled in the same environment) lead to a consistent value for the ratio $(^{129}\mathrm{Xe}/^{132}\mathrm{Xe})_e$, where $(^{129}\mathrm{Xe}/^{132}\mathrm{Xe})_e$ denotes the $^{129}\mathrm{Xe}/^{132}\mathrm{Xe}$ ratio that would eventually be reached in the ambient gas if all radiogenic xenon-129 were mixed with it? $(^{129}\mathrm{Xe}/^{132}\mathrm{Xe})_e$ is given by:

$$\left(\frac{^{129}\mathrm{Xe}}{^{132}\mathrm{Xe}}\right)_e = b + c\exp\left(-\Delta t/\tau_{129}\right) \qquad (4)$$

In the equation:

$$c = \left(\frac{^{129}\mathrm{I}}{^{127}\mathrm{I}}\right)_0 \left(\frac{^{127}\overline{\mathrm{I}}}{^{132}\overline{\mathrm{Xe}}}\right) \qquad (5)$$

where $(^{129}\mathrm{I}/^{127}\mathrm{I})_0$ is the ratio of radioactive to stable iodine at the beginning of the decay interval, and $(^{127}\overline{\mathrm{I}}/^{132}\overline{\mathrm{Xe}})$ is the average ratio of iodine-127 and xenon-132 in the entire mixing volume for the ambient xenon.

From equations (4) and (5) it is apparent that if b is plotted against $\exp(-\Delta t/\tau_{129})$ for three or more separated phases of the same meteorite, a linear relation should be defined. Its intercept is the parameter $(^{129}\mathrm{Xe}/^{132}\mathrm{Xe})_e$ that is characteristic of the environment of the meteorite, and the slope is $-(^{129}\mathrm{I}/^{127}\mathrm{I})_0(^{127}\overline{\mathrm{I}}/^{132}\overline{\mathrm{Xe}})$. Reynolds *et al.* have not yet obtained sufficient data on separated phases to study the adherence to equations (4) and (5), but it is evident that these relations do provide a powerful means of checking the validity of the assumption of evolution in a closed environment.

(4) *The environment parameter.* Let us assume that equations (4) and (5) will be found to be as much in accordance with future data on separated phases as equations (2) and (3) are with existing data for whole meteorites: then it will be possible to use the parameter $(^{129}\mathrm{Xe}/^{132}\mathrm{Xe})_e$ in a unique way. We have found that this parameter should characterize the mixing volume of the meteorite's environment (which may and probably does include a large fraction of the interior of the meteorite's parent body) rather than the meteorite itself. Hence it will be appropriate to call it the 'environment parameter'. Every meteorite formed in the same mixing volume should exhibit the same environment parameter, when correlation runs are performed on separated phases and interpreted according to equations (2), (3), (4) and (5). Conversely, meteorites formed in different environments—and by different we mean environments possessing appreciably different values for c—should be characterized by diverse values for the environment parameter.

The significance of the mixing volume is increased owing to the fact that it should represent at least the volume which participates in the common magmatic pool from which meteoritic minerals formed. If two meteorites were found to represent different mixing volumes, then it is very unlikely that they formed by differentiation from a common magmatic pool.

Thus, through studying the environment parameters of meteorites of different types it should be possible to learn whether it is correct to regard them as originating in the same parent object. And it may be possible in this way to gain new insight into the significance of the high- and low-iron groups of chondrites[26], the gallium–germanium groups of meteorites[27] and the clusters of cosmic ray ages[28,29].

Since c is determined by equation (4), and the ratio $(^{129}\mathrm{I}/^{127}\mathrm{I})_0$ is fixed by the nucleosynthetic model used, the ratio $(^{127}\overline{\mathrm{I}}/^{132}\overline{\mathrm{Xe}})$ would also be determined in such a study and could be used in a manner somewhat similar to that proposed for the environment parameter.

We thank Prof. John Reynolds, Mr. Craig Merrihue and Mr. Robert Pepin for several helpful discussions, and for making many experimental results available to us in advance of publication. We are particularly indebted to them for their permission to quote new results from the meteorite Abee, and to mention in a general way the preliminary results of other experiments that they will report in detail. Lacking this documentation, it would have been necessary to leave Parts 1 and 2 of the last section in as speculative a form as Parts 3 and 4. We are also grateful to Profs. V. Rama Murthy and Stanley L. Miller for their advice and helpful criticisms.

EXISTENCE OF WEAK *R*-TYPE IONIZATION FRONTS

By R. D. MEDFORD, A. L. T. POWELL and W. H. W. FLETCHER

Atomic Weapons Research Establishment, Foulness, Southend-on-Sea

THE theoretical work of Kahn[1] and Goldsworthy[2] on the gas dynamical effects of ionized H_{II} regions associated with the formation of *O* and *B* stars has enabled them to predict the formation of weak *R*-type ionization fronts in interstellar gas. Axford[3] has also examined the existence of weak *R*-type fronts and has discussed the anomaly introduced by the Chapman–Jouguet hypothesis which shows that they cannot exist.

In this article we give some evidence for the existence of weak *R*-type ionization fronts obtained during investigations of electromagnetically driven planar shock waves in the laboratory. Although we do not claim conclusive evidence, we think that the observed phenomenon is sufficiently interesting to be released before the publication of our main body of work elsewhere, and hope that it will help to resolve the anomaly studied by Axford.

Fig. 1 is a picture of streak (distance-time) and interference fringe photographs of the plasma motion superimposed on the same emulsion. Conditions under which this picture was taken are: 10-kV, 10-μF condenser used to drive the plane shock tube, which is filled with deuterium gas, at an ambient pressure of 4 mm mercury. Fringe shifts may be taken as directly proportional to the electron density in the plasma[4], and the dimensions of the shock tube[5] are such that one fringe shift represents an electron density increase of $0{\cdot}9 \times 10^{17}$ cm^{-3}. It will be seen that there are two distinct discontinuities in electron density demarcated by the fringe shifts, the second one coinciding with a visible luminous front. There is also a faint luminous front which coincides with the first discontinuity in electron density, but it is not possible to see it in Fig. 1 because self-light from the plasma has been deliberately attenuated to increase fringe definition[4]. A streak picture of the plasma taken without the superimposed interference fringes is shown in Fig. 2 to make this point clear. The interesting thing here is that the electron density behind the first front reaches an equilibrium, that is, the fringes pass through the first front, are displaced by a fixed amount and then remain parallel until they intersect the second front. At the second front they are further displaced until they attain a maximum shift in the direction of increasing electron density, after which they return to the undeflected position.

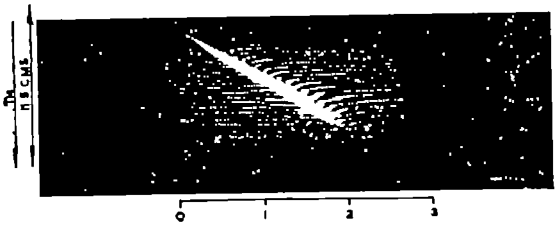

Fig. 1

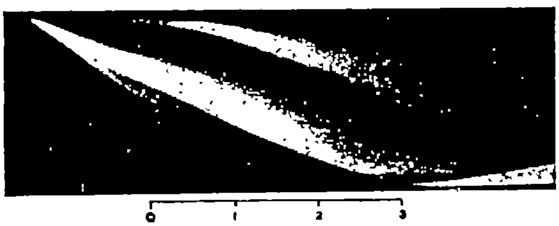

Fig. 2

Fig. 3 is an enlarged tracing of a typical fringe passing through the two luminous fronts and may be taken to be a graph of electron density with time at a fixed position in the shock tube. We now discuss possible explanations of the profile:

(1) Even though the electron density reaches equilibrium behind the first front it is difficult to see how the front can be contiguous with a classical strong shock discontinuity. Strong shock computations by Niblett[6] show that there should be $2{\cdot}2 \times 10^{16}$ free electrons cm^{-3} behind a shock front moving at 5×10^{6} cm sec^{-1} into deuterium at an ambient pressure of 4 mm mercury, and we have only 7×10^{16} cm^{-3} behind the first front.

(2) The Rosenbluth snowplough model[7] does not provide a satisfactory explanation even if we postulate a probability that a particle is swept up (Philips[8]), because it is concerned only with a thin sheath of ionized particles and we have here a relatively thick zone of ionized gas containing a second discontinuity of electron density.

(3) The flow pattern suggested by Goldsworthy and Axford of a weak *R*-type ionization front propagating ahead of a shock wave appears to fit the profile better. In their model the ionization is produced in the first front by ultra-violet radiation with quantum energies above the ionization potential. If the front advances with supersonic speed relative to the sound speed in the gas upstream and the ionized gas downstream of the front it is designated weak *R*-type. The weak *R*-type ionization front is followed by an 'isothermal' shock, and the ionizing radiation from the star is assumed to pass through the isothermal shock without absorption.

In applying this to the laboratory experiment the difficulty is to identify the source of radiation, which must, of course, be behind the second front, and since the ionization front moves at 5×10^{6} cm sec^{-1} it must provide about $3{\cdot}5 \times 10^{23}$ photons cm^{-2} sec^{-1} with energies above the Lyman limit. The emittance of ionizing photons at temperatures of 10^{6}, 10^{5} and 10^{4} °K were computed assuming the Planck distribution law. These are $1{\cdot}4 \times 10^{29}$, $1{\cdot}4 \times 10^{26}$ and $1{\cdot}5 \times 10^{20}$ cm^{-2} sec^{-1} respectively. Assuming that the radiation is bremsstrahlung from a slab of thickness 1 cm, we obtain much lower values of $1{\cdot}3 \times 10^{20}$, $3{\cdot}2 \times 10^{19}$ and $3{\cdot}2 \times 10^{14}$ ionizing photons cm^{-2} sec^{-1}. We therefore deduce that a black-body temperature between 10^{4} and 10^{5} °K

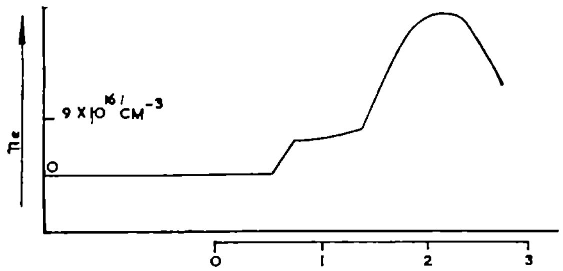

Fig. 3

would be an adequate source if we assume no loss mechanism.

There is some evidence to fix the radiation source at the current sheet because it has been observed that when the current has been short-circuited by a delayed discharge in the gas, which may contain impurities left behind at the wall, that the first luminous front starts to pull back into the second front (Fig. 2). Another possible source of radiation could be an impurity line radiator the frequency of which is close to the Lyman limit. Further evidence to support the existence of a weak R-type front is that the mean free path for photo-ionization ($\frac{1}{2}$ cm at 4 mm mercury at the Lyman limit) is of the same order as the front width.

Although more evidence must be obtained before the existence of a weak R-type system can be substantiated, the facts, so far as are known, in this experiment certainly indicate the existence of such a system.

We thank Dr. F. A. Goldsworthy for stimulating discussions.

RESONANCE INTERACTIONS OF FLUORESCENT ORGANIC MOLECULES IN SOLUTION

By Dr. J. B. BIRKS and L. G. CHRISTOPHOROU

Department of Physics, University of Manchester

THE quantum efficiency of the characteristic fluorescence of aromatic molecules in solution decreases at high concentrations. This effect, known as concentration quenching, appears to be general, and is due to interactions between excited and unexcited molecules of the same kind. In some compounds the decrease in intensity of the normal structured emission band M, with increase in concentration c, is accompanied by the appearance of a broad structureless emission band D at longer wavelengths which increases in intensity with increase in c (ref. 1). M is characteristic of the excited unassociated (monomer) molecules: D is characteristic of excited dimers formed by the association of excited and unexcited molecules.

We may distinguish four types of concentration-dependent behaviour in solutions of fluorescent aromatic compounds.

(I) The appearance of the emission D at high c is accompanied by a new absorption band D_0 at longer wave-lengths than the normal (monomer) absorption band M_0. This behaviour, which is exhibited by perylene and anthranthrene, is attributed to the formation of fluorescent excited dimers which are also stable in the ground-state.

(II) The appearance of D is not accompanied by any changes in the absorption spectrum at high c. This behaviour is exhibited by pyrene[2] and 1:2-benzanthracene and by many of their derivatives[1] (Table 2). It is attributed to the formation of fluorescent excited dimers, known as excimers[3], which are not stable in the ground-state. The excimer emission D is accompanied by dissociation.

(III) Anthracene exhibits concentration quenching and a change in the absorption spectrum at short wave-lengths at high c following photo-excitation[4], but no emission D is observed[1]. This behaviour has been shown to be due to the formation of a non-fluorescent excited dimer (dianthracene) which is stable in the ground state.

(IV) In other compounds concentration quenching occurs, but there is no emission D and no change in the absorption spectrum. By analogy to I–III, this behaviour may be attributed to the transient formation of non-fluorescent dimers which are not stable in the ground state.

These four types of behaviour are summarized in Table 1.

Table 1

Type	Concentration quenching	Dimer emission	Dimer absorption
I	Yes	Yes	Yes
II	Yes	Yes	No
III	Yes	No	Yes
IV	Yes	No	No

Table 2 lists the properties of all the compounds which we have so far observed to exhibit excimer emission, that is, Type II behaviour. The wave-lengths in nm (mμ) of the first vibrational peak M_1 in the monomer emission spectrum (observed at low c to minimize self-absorption) and of the peak D_1 of the excimer emission spectrum, and the energy difference $\nu^1(M_1-D_1)$ in cm.$^{-1}$ between M_1 and D_1 are tabulated. The peak $M_1 = 341$ nm in 2,5 diphenyloxazole (PPO) is only observed at $c \leqslant 10^{-4}M$, and is absent from the spectrum reported by Weinreb[5].

The effects so far considered are due to interactions between identical molecular species, which are naturally in resonance. We wish now to report a new phenomenon, the resonance interaction between

two different molecular species A and B to form excited 'mixed dimers' $(AB)^*$ which may be either fluorescent or non-fluorescent.

We have compared the fluorescence spectra of solutions containing the following molar concentrations: (i) c of A, (ii) c of B, and (iii) c of A and c of B (prepared by mixing equal volumes of solutions containing $2c$ of A and $2c$ of B respectively). A and/or B are compounds which exhibit excimer emission. In general, if the first singlet π-excitation energy is S_1, and if $S_1(A) > S_1(B)$, non-radiative energy transfer occurs between A and B due to dipole-dipole inductive interaction[6] and the excitation energy becomes localized on B, the species with the lower value of S_1 (ref. 7). The magnitude of this non-radiative transfer and also of the corresponding radiative transfer process, depends on the degree of overlap of the emission spectrum of A and the absorption spectrum of B. In our experiments A and B are chosen as having very similar values of S_1 so that $S_1(A) - S_1(B) \leqslant 120$ cm.$^{-1}$. This minimizes the A–B spectral overlap, inhibits preferential energy transfer from A to B, and also establishes resonance between A and B.

Fig. 1 shows the observed spectra for A = pyrene, B = 1-methyl pyrene, at $c = 5 \times 10^{-3}M$. The scale of relative quantum intensity for the individual solutions of A and B is halved prior to plotting to allow for the fact that in the mixed solution half the incident light is absorbed by each of the solutes. If A and B did not interact, the resultant fluorescence spectrum of the mixture would be the sum $(A + B)$ of the spectra of the two components. The difference by a factor of 2 between the excimer components of the observed mixture spectrum Z and $(A + B)$ is therefore attributed to emission by 'mixed excimers' $(AB)^*$ formed by the diffusional collision and resonance interaction of A^* and B and of B^* and A.

Similar behaviour has been observed in the following pairs of compounds: 4-methyl pyrene and 1-methyl pyrene; 1:2-benzanthracene and 6-methyl 1:2-benzanthracene; 5-methyl 1:2-benzanthracene and 6-methyl 1:2-benzanthracene.

Fig. 2 shows the observed spectra for A = pyrene B = 3:4 benzphenanthrene, at $c = 5 \times 10^{-3}M$. 3:4 benzphenanthrene exhibits type IV behaviour (Tabl 1). In this case the relative intensity of the excime component of the mixture spectrum Z is only 0· that of the sum spectrum $(A + B)$. This is attribute to the formation of non-fluorescent 'mixed dimers' $(AB)^*$ by the resonance interaction of A^* and B and of B^* and A. Similar behaviour has been observed with A = pyrene, B = 6-methyl 1:2 benzanthracene, showing that even if both component

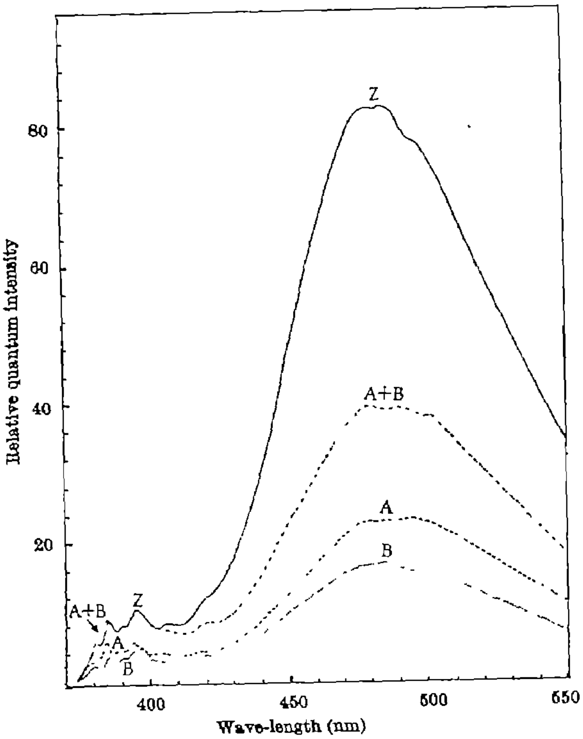

Fig. 1. Fluorescence spectra of solutions in cyclohexane. A, 5×10^{-3} M pyrene, B, 5×10^{-3} M 1-methyl pyrene; Z, 5×10^{-3} M pyrene and 5×10^{-3} M 1-methyl pyrene

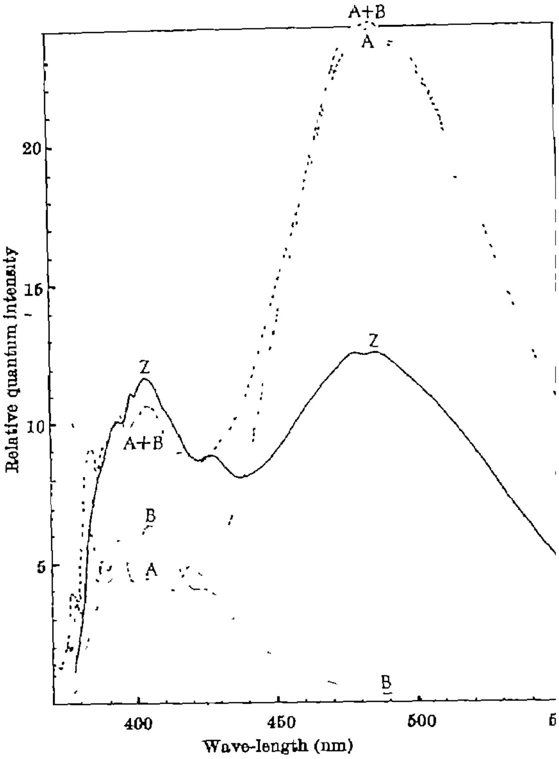

Fig. 2. Fluorescence spectra of solutions in cyclohexane. A, 5×10^{-3} M pyrene, B, 5×10^{-3} M 3 : 4-benzphenanthrene; Z, 5×10^{-3} M pyrene and 5×10^{-3} M 3 : 4-benzphenanthrene

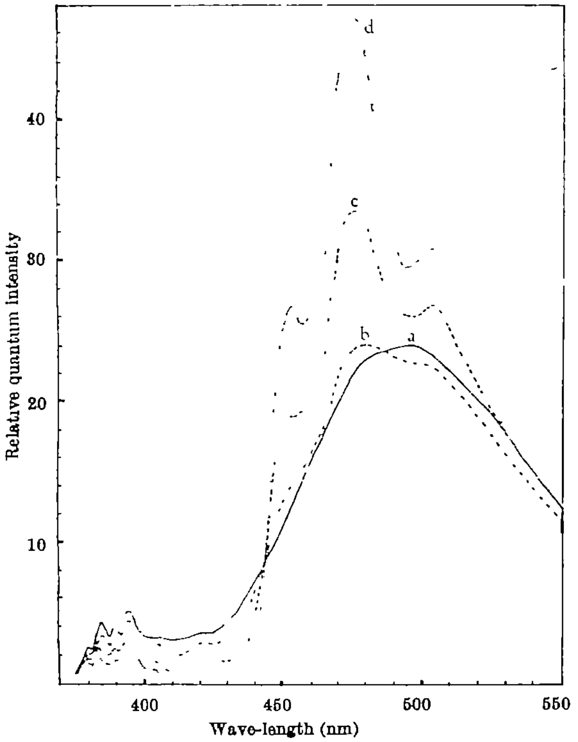

Fig. 3. Fluorescence spectra of solutions in benzene. *a*, $1\cdot1 \times 10^{-3}$ *M* pyrene, *b*, $1\cdot1 \times 10^{-3}$ *M* pyrene and $1\cdot1 \times 10^{-5}$ *M* perylene, *c*, $1\cdot1 \times 10^{-3}$ *M* pyrene and $5\cdot5 \times 10^{-5}$ *M* perylene; *d*, $1\cdot1 \times 10^{-3}$ *M* pyrene and $1\cdot1 \times 10^{-4}$ *M* perylene

form fluorescent excimers (Table 2), their 'mixed dimers' may be non-fluorescent if their molecular shapes differ. In this one case $S_1(A) - S_1(B) = 1040$ cm.$^{-1}$ but the energy transfer is sufficiently small to be neglected.

Hochstrasser[8] observed a band in the fluorescence spectrum of a solid solution of perylene in crystalline pyrene, intermediate in wave-length between the spectra of crystalline pyrene and crystalline perylene which he attributed to a 'mixed dimer' emission. Fig. 3 shows the effect of the addition of perylene on the fluorescence spectrum of a concentrated solution of pyrene in benzene. The strong emission band which appears in the 480-nm region is due to the perylene monomer emission *M*, excited preferentially by energy transfer from the pyrene.

It is possible that the similar band observed in the crystalline solution spectrum has a similar origin.

We may summarize the behaviour of the excited 'mixed dimers' so far observed in terms of the four types I-IV (Table 1).

(*a*) II + II→II (molecules of similar shape).
(*b*) II + II→IV (molecules of different shape).
(*c*) II + IV→IV

In addition, Furst and Kallmann[9] have observed cross concentration quenching between molecules of anthracene and 2-methyl anthracene. Anthracene is of type III and so probably is 2-methyl anthracene, so that we have:

(*d*) III + III (or IV)→IV (or III).

The possibility of stable 'mixed dimers' is an interesting one, and this and other possible types of 'mixed dimer' behaviour are at present being studied.

This work was partially supported by a grant from the British Empire Cancer Campaign.

NICOTINAMIDE 6-MERCAPTOPURINE DINUCLEOTIDE AND RELATED COMPOUNDS: POTENTIAL SOURCES OF 6-MERCAPTOPURINE NUCLEOTIDE IN CHEMOTHERAPY

By DR. M. R. ATKINSON, J. F. JACKSON, PROF. R. K. MORTON and A. W. MURRAY

Department of Agricultural Chemistry, Waite Agricultural Research Institute, University of Adelaide

WE[1] have previously shown that an enzyme from liver nuclei catalyses the formation of dinucleotides from a number of compounds which resemble the natural substrates (nicotinamide mononucleotide and nicotinic acid mononucleotide, and adenosine triphosphate) thus:

$$\begin{array}{c}\text{substituted-}\\\text{pyridine}\\\text{mononucleotide}\end{array} + \begin{array}{c}\text{purine}\\\text{nucleoside}\\\text{5}'\text{-triphosphate}\end{array} \overset{\text{transferase}}{\rightleftharpoons} \begin{array}{c}\text{substituted-}\\\text{pyridine}\\\text{purine}\\\text{dinucleotide}\end{array} + \begin{array}{c}\text{pyro-}\\\text{phosphate}\end{array}$$

An impure sample of 6-mercaptopurine riboside 5′-triphosphate inhibited adenylyl transfer from adenosine triphosphate to nicotinamide mononucleotide; the reaction products contained traces of a new dinucleotide which had the properties expected of nicotinamide 6-mercaptopurine dinucleotide[1]. This and some related compounds are described here: they have potential value in cancer chemotherapy.

Nicotinamide 6-mercaptopurine dinucleotide. Nicotinamide 6-mercaptopurine dinucleotide has now been prepared from the two mononucleotides in a yield of 20–25 per cent by treatment with dicyclohexylcarbodiimide in aqueous pyridine, a method used by Todd *et al.*[2] for synthesis of nicotinamide adenine dinucleotide (coenzyme I). The compound was purified by ion-exchange chromatography on 'Dowex-2' (formate form) and electrophoresis on paper at *p*H 4·1 in 50 mM acetic acid–50 mM formic acid–50 mM triethylamine. It had the same electrophoretic mobility in this system as nicotinamide hypoxanthine dinucleotide. At *p*H 5, the absorption maxima were at 266 mμ (mε, 6·6) and at 321 mμ (mε, 23·4).

This new analogue of coenzyme I was reduced enzymatically with alcohol dehydrogenase at pH 9·5 in 0·3 M ethanol–0·1 M glycine. The maximum absorption of the reduced form was at 311 mμ (mϵ, 22·4); the increase in absorption at 340 mμ (Δmϵ, 5·9, based on phosphorus analysis) on reduction of the oxidized form was the same as that reported for coenzyme I (ref. 3). Nicotinamide mercaptopurine dinucleotide was also reduced with dihydrolipoamide and dihydrolipoamide dehydrogenase, and was hydrolysed to its constituent mononucleotides by nucleotide pyrophosphatase.

The dinucleotide obtained by chemical synthesis had the same electrophoretic mobility as the nicotinamide mercaptopurine dinucleotide obtained by the action of the nuclear transferase. In a coupled enzymatic assay with nicotinamide mononucleotide and the appropriate purine riboside triphosphate, together with the transferase, ethanol and alcohol dehydrogenase, formation of the reduced dinucleotide was measured at 340 mμ; the relative rates at pH 8 were: with 0·4 mM adenosine triphosphate, 100 units, with 0·4 mM mercaptopurine riboside 5′-triphosphate, 7 units, and with 0·4 mM hypoxanthosine triphosphate, less than 3 units. These results clearly confirm that 6-mercaptopurine riboside 5′-triphosphate is a substrate of the nuclear transferase[1].

6-Mercaptopurine riboside 5′-triphosphate. By a combination of paper electrophoresis and chromatography in isobutyric acid–ammonia, 6-mercaptopurine riboside 5′-triphosphate has now been purified. At pH 4·1, this compound has the same electrophoretic mobility as hypoxanthosine triphosphate. It is a substrate of hexokinase, and one equivalent of reduced nicotinamide adenine dinucleotide phosphate (reduced coenzyme II) was formed in an assay with the coupled reactions:

$$\begin{array}{c}\text{mercaptopurine}\\\text{riboside}\\\text{triphosphate}\end{array} + \text{glucose} \rightarrow \begin{array}{c}\text{mercaptopurine}\\\text{riboside}\\\text{diphosphate}\end{array} + \begin{array}{c}\text{glucose}\\\text{6-phosphate,}\end{array}$$

and

$$\begin{array}{c}\text{glucose}\\\text{6-phosphate}\end{array} + \begin{array}{c}\text{oxidised}\\\text{coenzyme II}\end{array} \rightarrow \begin{array}{c}\text{6-phospho-}\\\text{gluconic acid}\end{array} + \begin{array}{c}\text{reduced}\\\text{coenzyme II,}\end{array}$$

using hexokinase and glucose 6-phosphate dehydrogenase.

In confirmation of the previous finding with impure material[1], purified 6-mercaptopurine riboside 5′-triphosphate is a potent inhibitor of adenylyl transfer to nicotinamide mononucleotide catalysed by the nuclear adenylyl transferase. In the coupled assay with the transferase and alcohol dehydrogenase at pH 8, K_m for adenosine triphosphate was $7{\cdot}4 \times 10^{-5}$ M and K_i for 6-mercaptopurine riboside 5′-triphosphate was 5×10^{-5} M.

Formylaminoimidazolethioamide nucleotide. During the preparation of crystalline pyridinium 6-mercaptopurine riboside 5′-monophosphate, it was found that this nucleotide was partly converted into a new nucleotide which had 25 per cent greater anionic mobility on electrophoresis at pH 4·1. The new nucleotide was isolated by paper electrophoresis; it had maximum absorption at 280 mμ, was hydrolysed to a nucleoside by 5′-nucleotidase, and was converted rapidly into 6-mercaptopurine nucleotide in 0·15 N sodium hydroxide and more slowly at pH 9. This compound is very probably the nucleotide of formylaminoimidazolethioamide, an analogue of the natural precursor (the nucleotide of formylaminoimidazolecarboxamide) which forms hypoxanthosine 5′-monophosphate in the cell[4].

Lethal synthesis in malignant cells. Recent investigations indicate that 6-mercaptopurine nucleotide and its metabolic products are responsible for the effects of 6-mercaptopurine in chemotherapy[1]; resistance to the drug appears to be due to the failure of entry into the tumour cell, or to decreased synthesis of the nucleotide after uptake of the free base[5]. The inhibition of the nuclear adenylyl transferase by 6-mercaptopurine riboside 5′-triphosphate may largely account for the selective action of 6-mercaptopurine against certain tumours[1]. The ease with which derivatives of 6-mercaptopurine are modified by oxidative and hydrolytic enzymes, and by enzymes which catalyse group transfer reactions, suggests that certain derivatives of 6-mercaptopurine mononucleotide, such as dinucleotides, polynucleotides, diesters and nucleoside 3′-5′-cyclic phosphates, may be converted into active antimetabolites within the cell by lethal enzymatic reactions. The ready conversion of derivatives of aminoimidazolethioamide into 6-mercaptopurine derivatives as found by Shaw and Butler[6], and especially the apparent conversion of formylaminoimidazolethioamide nucleotide into 6-mercaptopurine nucleotide as described here, suggests that this class of compound may be a source of 6-mercaptopurine nucleotide in cells resistant to 6-mercaptopurine. These compounds are now being studied, along with analogues of nicotinamide nucleotides[7].

ESTIMATION OF MOLECULAR WEIGHTS OF PROTEINS BY GEL FILTRATION

By Dr. P. ANDREWS

National Institute for Research in Dairying, Shinfield, Reading

GEL filtration is a fractionation method which utilizes the 'reversed' sieving properties of a bed of porous gel granules. During passage through the bed, solute molecules which are small enough to penetrate the porous gel are retarded relative to larger molecules unable to enter the pores. Its application to large molecules was demonstrated by Lathe and Ruthven[1], who achieved some separation of polypeptides and proteins on columns of starch grains. They also proposed the method as a means of molecular weight estimation, and reported interesting results in this connexion; but their starch columns did not effect enough separation between different proteins for the idea to be developed further. The at present available 'Sephadex' gel filtration media have the same disadvantage. However, agar gels[2-4] and synthetic polymer gels[5,6] are effective for separating a variety of macromolecules, so they provide a means of testing Lathe and Ruthven's suggestion.

For this purpose it is desirable to know the molecular weight range over which a gel functions optimally. In practice, each gel separates solute molecules of a wide range of molecular weights, indicating that the pore size in the gel is far from uniform. However, the inverse relationship between concentration of gel-forming substance and mean pore diameter[3,7] suggests that gels of different concentration will give optimal separation in different molecular weight ranges, the more dilute gels being better for larger molecules. This effect has now been studied with agar gels, using proteins as solute molecules, and the gel filtration technique applied to the estimation of protein molecular weights.

Preparation of agar gels and columns. Gels were prepared by heating mixtures of agar (standard grade; Davis Gelatine, Ltd., Warwick) and water at 90° with stirring until the water was all absorbed, then autoclaving the swollen agar at 15 lb./sq. in. pressure until it had liquefied completely. Autoclaving for 45–60 min was required for gels containing 9 and 12 per cent by weight of agar, but 20–30 min was sufficient for less-concentrated ones. The gels were allowed to cool at room temperature for at least 12 h before being disintegrated in a rotating-blade homogenizer ('Atomix'; M.S.E., Ltd.) run at full speed, water being added as required. The temperature was kept below 30°. Slurries of granules prepared in this way were easily pushed through standard sieves for grading according to size with the aid of a broad flat spatula. The treatment needed to give a good yield of granules of the required size varied with the gel, but was soon determined by experiment. The sieved granules were thoroughly washed with water, the washings being decanted. Prepared in this way, granules have been stored under water in the cold for several months without noticeable change.

To facilitate the correlation of results, all experiments were performed with gel columns measuring 2·5 × 50 cm. These were prepared by pouring aqueous suspensions of gel granules into vertical glass chromatographic columns, and allowing the water to flow through under gravity, until beds 53–55 cm long were obtained. When a small pressure was applied these columns shrank to about 50 cm long, and when composed of 100–200 mesh granules had flow-rates of 10–30 ml./h except in the case of 2·5 per cent agar, where 60–100 mesh granules afforded a maximum flow-rate of only about 5 ml./h. Experiments with 9 per cent agar showed that proteins were eluted from columns of 100–200 mesh granules as rather sharper bands than from 60–100 mesh granules (cf. Flodin[8]), but changes in flow-rate in the above range had no effect on the separations.

Washing and equilibration of the columns with buffer solutions reduced contamination of the effluent to the following: optical density, about 0·02 at 260 and 280 mμ, about 0·05 at 215 mμ (1 cm cell); carbohydrate, 1–3 μg/ml. (estimated as hexose). These values were further reduced by use or prolonged washing.

Table 1. MOLECULAR WEIGHTS AND DIFFUSION COEFFICIENTS OF PROTEINS USED AS STANDARDS IN GEL FILTRATION EXPERIMENTS

Protein*	Molecular weight†	Diffusion coefficient† cm²/sec × 10⁷
α-Lactalbumin	16000	10·6
β-Lactoglobulin	36000	7·8
Serum albumin	70000	5·9
γ-Globulins (human)	160000	c. 4·5
Thyroglobulin	670000	2·5

* All the proteins except γ-globulins are of bovine origin.
† Data are taken from recent literature.

Effect of agar concentration on separation of proteins. Separation between the compounds listed in Table 1 was attempted with columns of gel ranging from 2½ to 12 per cent in agar concentration, equilibrated with 0·04 M potassium phosphate buffer pH 7·0 containing 0·12 M potassium chloride. The tops of the columns were very susceptible to disturbance, so that the samples, dissolved in buffer (2 ml.), were applied by layering under buffer. Cytochrome *c* (2 mg) was regularly included to provide a visual check for even flow and a guide to the progress of a separation. Indian ink was unsuitable for either purpose because it was partially adsorbed on the gel. Hog gastric mucoid behaved as though completely excluded from all the gels except the 2½ per cent one, and even in this case the eluted peak had a sharp leading edge, indicating exclusion of some of the larger molecules. Hog gastric mucoid, cytochrome *c*, and the colourless proteins were estimated spectrophotometrically at 215, 412 and 280 mμ respectively. In each experiment the column effluent was collected in 3 ml. fractions, beginning when the sample had just entered the column, and the precise volume collected at the emergence of the maximum of each solute peak ('peak volume') was derived from a plot of the optical density of the fractions comprising the peak. To facilitate comparisons, the peak volume of hog gastric mucoid, which varied a little with different gels,

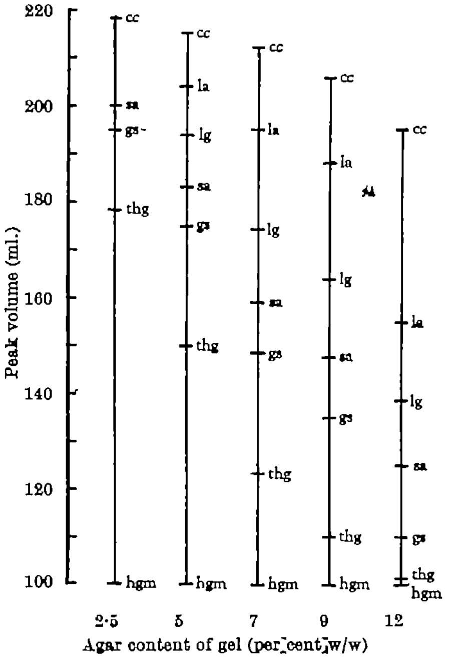

Fig. 1. Effect of agar content of gels on protein separation by gel filtration. See text for experimental details; cytochrome *c* is retarded during passage through the columns by ion-exchange effects. Abbreviations: cc, cytochrome *c*; la, α-lactalbumin, lg, β-lactoglobulin; sa, bovine serum albumin; gs, human γ-globulins; thg, bovine thyroglobulin; hgm, hog gastric mucoid

is taken as constant, and the other figures corrected accordingly. Fig. 1 shows the results of these experiments. Their reproducibility is demonstrated by the fact that separation between the peak volumes of serum albumin and α-lactalbumin varied only between 38 ml. and 42 ml. in several dozen runs with columns composed of the same preparation of 9 per cent agar gel granules.

As anticipated, decrease in the agar content of the gels shifted their effective range, the ability to separate the smaller protein molecules giving way to an ability to distinguish between larger ones. Two typical separations are illustrated in Fig. 2. Peak-widths for compounds retarded during passage through the columns were about the same in all experiments, the 'spreading' in 5 per cent agar mentioned by Polson[8] not being observed. The recovery of compounds in Fig. 1 was 85–100 per cent with quantities in the range 2–20 mg, but lower for cytochrome *c* on freshly prepared gels.

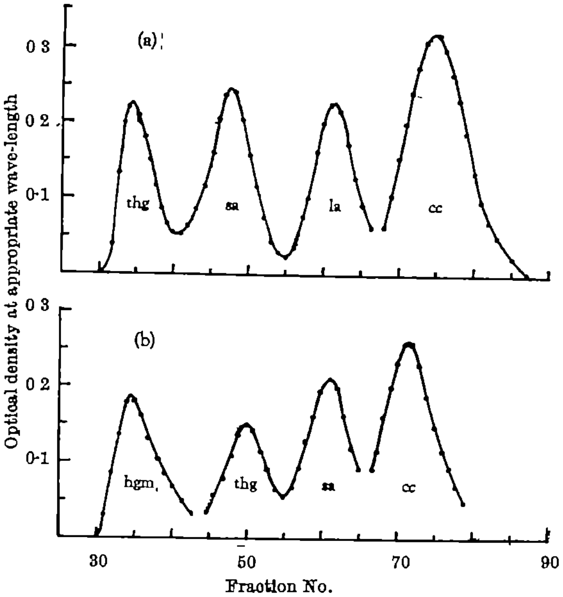

Fig. 2. Separation of proteins by agar-gel filtration. *a*, On a column of 9 per cent agar equilibrated with 0·04 M *tris* *p*H 7·5 + 0·12 M potassium chloride. Cytochrome *c* is retarded by ion-exchange effects. *b*, On a column of 5 per cent agar, equilibrated with 0·04 M phosphate *p*H 7·0 + 0·12 M potassium chloride. Interaction between agar and cytochrome *c* is less than in *tris* buffer. Abbreviations : see Fig. 1

In further experiments, a change from phosphate to *tris*(hydroxymethyl)aminomethane (*tris*) buffers in the range *p*H 7–8, containing various amounts of potassium chloride up to 0·36 M, was found to have no effect on separations between the proteins of Table 1, all of which have isoelectric points below *p*H 7. However, passage of the basic protein cytochrome *c* through the columns was accelerated, relative to the other proteins, by increasing salt concentrations, so demonstrating the cation-exchange properties of agar[9]. The retardation of cytochrome *c* by ion-exchange was apparently eliminated by addition of 0·24 M potassium chloride to the eluting buffers (0·04 M *tris* or potassium phosphate *p*H 7·5), since further addition of salt had no effect on its movement relative to the other proteins, and its behaviour then corresponded to that expected for a protein of molecular weight 13,000. Ion-exchange effects may be avoided by using columns of agarose[9], the neutral polysaccharide constituent of agar, but as both starch[1] and 'Sephadex'[10-12] also appear to possess ion-exchange properties, these effects may be difficult to avoid completely.

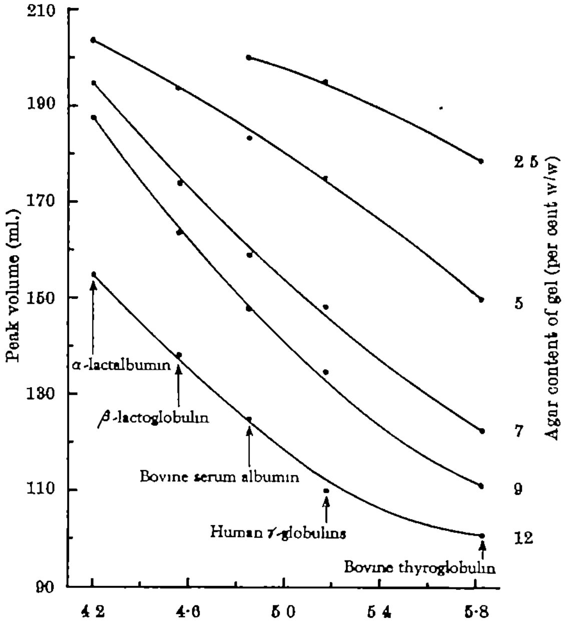

Fig. 3. Separation of 'standard' proteins. Plots of peak volumes against log molecular weights of proteins for gels of different agar content

Molecular weight estimation. A plot of peak volume against log molecular weight of the proteins listed in Table 1 gives, with the results for each gel, a smooth curve which approaches linearity in the molecular weight range where separation efficiency is optimal (Fig. 3). Granath and Flodin[13] observed a similar relationship in the results of gel filtration experiments with dextrans. Fig. 3 provides a means of estimating molecular weights of proteins from their gel filtration behaviour, and experiments to test its value were performed with 9 per cent agar columns.

Column runs were carried out, as already described, in the cold. Each sample consisted of crude or purified enzyme, cytochrome *c*, and sufficient of one or two of the 'standard' proteins (Table 1) for their peaks in the column effluent to be clearly distinguished from the protein in the enzyme preparation. Enzymatic activities in the column fractions were assayed by the appropriate methods[14]; hæmoglobin was estimated spectrophotometrically at 410 mμ. The peak volumes for standard proteins and enzymes were read from the elution diagrams. The width of enzyme and standard protein peaks were about the same. Refinements in technique such as described by Hjertén and Mosbach[9] could result in some reduction of peak-width, but may have little effect on the precision with which the separation between maxima can be measured. To detect interaction with the agar, each enzyme was run in the presence of two different salt concentrations (buffer plus 0·12 and 0·24 M potassium chloride). The behaviour of the alkaline phosphatases was most influenced by salt concentration, but slight effects also occurred with hæmoglobin and malic and isocitric dehydrogenases. However, as with cytochrome *c*, increase in salt concentration above 0·24 M had no further effect.

Of the enzymes used in these experiments, rennin and milk alkaline phosphatase (generously provided by Dr. G. C. Cheeseman and Dr. R. L. J. Lyster, respectively) were highly purified, the mammary tissue glucose 6-phosphate dehydrogenase was in a crude particle-free tissue extract, and the remainder were commercial partially purified samples. The hæmoglobin was a crystalline sample.

Results of the molecular weight estimations are collected in Table 2. Agreement with recent values determined by the usual physical methods is generally good. The gel filtration result for rennin favours the lower, more recent, literature value[16], and agrees well with a molecular weight of about 32,000 calculated by Dr. G. C. Cheeseman from amino-acid analyses (personal communication). Bovine hæmoglobin was applied to the columns as a 0·06 per cent w/v solution, and during the runs this concentration decreased. The value obtained for its molecular weight indicates dissociation into half-molecules under these conditions, a result agreeing with Gutfreund's observations[22] on very dilute hæmoglobin solutions. The separation between bovine serum albumin and rabbit hæmoglobin on agar columns, reported by Polson[2], may well be due to dissociation of the latter protein, resulting in a considerable molecular weight difference between the two proteins, rather than, as suggested, to the small difference between their diffusion coefficients.

Table 2. PROTEIN MOLECULAR WEIGHTS ESTIMATED BY GEL FILTRATION

Protein (source)	Molecular weight: Estimate from gel filtration behaviour*	Molecular weight: Literature value(s)	Reference
Rennin (calf stomach)	30,000	40,000 34,400	15 16
Hæmoglobin (ox blood)	32,000	68,000	see text
Malic dehydrogenase (pig heart)	40,000	c. 50,000	17
Hexokinase (yeast)	47,000	45,000	18
Isocitric dehydrogenase (pig heart)	57,000 33,000†	60,000	19
Glucose 6-phosphate dehydrogenase (guinea pig mammary gland tissue)	74,000	—	—
Glucose 6-phosphate dehydrogenase (yeast)	89,000	—	—
Alkaline phosphatase (calf intestine)	92,000	100,000	20
Alkaline phosphatase (milk)	105,000	—	—
Alcohol dehydrogenase (yeast)	120,000	150,000	21

* Possible error due to uncertainty in values of peak volumes ± 6 per cent.

† ±10 per cent.

The isocitric dehydrogenase preparation (obtained from Boehringer and Soehne) apparently contained unequal amounts of two enzymatically active constituents, the minor one having roughly half the molecular weight of the other; but since the two components were not completely separated from each other, the precise estimation of peak volume for the minor component was not possible. The result for hexokinase confirms Schachman's value[18], which was measured at pH 8. The hexokinase gel filtration experiment and the enzyme assays were performed at pH 7·5, and all the activity was associated with the component of molecular weight 47,000. The results indicate that this is the size of the enzymatically active hexokinase molecule, while the value of 96,600, measured at pH 5·5 and so often quoted in the literature, represents a dimer. Molecular weight data for glucose 6-phosphate dehydrogenase have not been published, although the enzyme has recently been highly purified from yeast[23] and from cow mammary tissue[24]. Gel filtration indicates that the molecular weight of both this enzyme and alkaline phosphatase varies with the source.

Recovery of stable enzymes in the column effluents was 90–100 per cent, except in experiments with egg-white lysozyme, when none was detected. In such cases, where agar is unsuitable, polyacrylamide or another synthetic gel may be a satisfactory filtration medium.

The quantity of protein needed for molecular weight estimation by gel filtration depends on the specificity and sensitivity of methods for its detection, so that, particularly with enzymes, an extremely small amount is sufficient, and it is possible to estimate molecular weights in very dilute solution. In addition, purification of enzymes may well be unnecessary. Martin and Ames's ultracentrifugal method[25] has similar advantages but requires more elaborate equipment than does the gel filtration method, without necessarily having greater accuracy. Both methods have the disadvantage that, when applied to impure proteins, interaction between solute macromolecules is potentially a source of error. Further experiments should show the frequency of this occurrence.

Both the size and shape of molecules in solution probably influence their behaviour in gel filtration, so this method for estimating molecular weights has to be used with caution in relation to molecules that differ significantly in shape from those used as molecular weight standards. Judging from the results in this paper, the proteins listed in Table 1 are suitable for comparison with enzymes, most of which are believed to be globular proteins with a frictional ratio of about 1·15. However, the validity of the method for very large protein molecules has yet to be assessed.

Diffusion coefficients for the enzymes in Table 2 were also estimated from their gel filtration behaviour, using a graph of peak volume against diffusion coefficient of the standard proteins (Table 1) for interpretation. The values so obtained were on the average 11 per cent lower than the corresponding literature values. This disparity is about twice the average deviation from literature values for similarly estimated molecular weights. The conclusion is that, for enzymes at least, the method described here is probably of more value for estimating molecular weights than diffusion coefficients.

DEVELOPMENT OF CHROMOPHORES

Development of Chromophores in the Carbonyl-Amino System

THE main pathways in non-enzymatic browning appear to commence with carbonyl/amino group reactions, and αβ unsaturated carbonyls seem to be concerned in the development of the initial chromophores as opposed to the later production of larger brown polymers. We have mentioned[1] the isolation from glucose/glycine systems of a number of non-volatile, water-soluble carbonyl compounds, some of them of an αβ unsaturated nature, and at the time the work was progressing it was reported[2-4] that several unsaturated carbonyl compounds of unknown structure had been detected in stored foodstuffs. It was decided to compare the potentialities of saturated and unsaturated carbonyl compounds as chromophore developers, particularly in the presence of amino compounds, since these are also present in foods and since we had found that the carbonyl compounds isolated from the glucose/glycine system browned more readily on incubation with glycine than with glucose.

At the same time we were examining the effect of sulphites on the aldose/glycine system, and used the reactions of citral[5] with sulphites to interpret our results[6].

Citral is an αβ unsaturated carbonyl compound with a second non-conjugated double bond, and so should show the normal αβ unsaturated carbonyl reactions with amino groups in the absence of sulphite. In the presence of the same quantities of sulphite one might expect the initial reactions leading to chromophore development to be less hindered in the case of citral than in carbonyl compounds with only the αβ site available for co-sulphonation.

Preliminary comparative experiments showed that on incubation with glycine, αβ unsaturated carbonyl compounds developed chromophores faster than did saturated carbonyls and that the rate of chromophore development with citral decreased as the more sulphite (1–3 moles) was added to the system.

In this connexion it is worth mentioning that in our extensive experiments on the development of chromophores in sugar/amino systems it has appeared that for rapid initiation of colour development, a rapid development of unsaturation must occur, and agents or physical treatment which produce such unsaturation lead to rapid chromophore development. The presence of nitrogen functions leads to the early development of unsaturation and when unsaturated carbonyl compounds are present in the system the browning reaction is very much faster in the presence of a nitrogen function than in its absence.

Owing to the availability at the time, the first experiments were limited to a few representative carbonyl compounds. Citral (76 mg) was incubated with glycine (2 gm) in 2 : 1 methanol/water (30 ml.) at 50° C in the presence and absence of 1 equivalent of sodium metabisulphite. After 20 min the unsulphited sample was browning and within 24 h a brown polymer had separated. This polymer rapidly darkened owing to further polymerization. The sulphited citral showed no chromophore development after 2 months incubation. A comparison of glycine incubations with saturated and unsaturated aldehydes, namely, crotonaldehyde, butyraldehyde, 2 ethyl-*n*-hexanal, 2 ethyl hexene-2-al under similar incubation conditions (crotonaldehyde and 2 ethyl hexene-2-al were used at two concentrations) showed that initial chromophore development occurred earlier with the αβ unsaturated aldehydes, and that 2 ethyl hexene-2-al took much longer to discolour than crotonaldehyde or citral. None of the other mixtures developed any colour nor did a number of saturated ketones apart from *cyclo*pentanone. None of the sulphited aldehyde or ketone series developed any colour except crotonaldehyde, which developed a faint colour after 7 days incubation. It was noted that the presence of an ethyl substituent on the α-carbon atom greatly diminished the tendency to promote browning. In further studies 0·1 m.mole of the carbonyl compound was incubated in a screw-cap bottle with 0·6 m.mole of glucose and 1·3 m.moles of glycine in 1·0 ml. water and 2·0 ml. ethanol at 50° C. The compounds investigated in this experiment were butyraldehyde and crotonaldehyde; 2 ethyl hexanal and 2 ethyl-2-hexenal; caproic aldehyde and 2-hexenal. The tubes were examined visually and the shade and intensity of the colour was estimated. Table 1 summarizes the results.

It is clear that αβ unsaturated straight-chain aldehydes greatly accelerated the initial development of chromophores in this system as well, and that this effect was not shown by the unsaturated aldehyde with an ethyl substituent on the α-carbon atom. The saturated aldehydes appeared to have a slight retarding effect on colour development in the glucose/glycine series.

In similar glucose/glycine reaction systems we found that the major losses of sulphite were not mainly due to conversion to sulphate, and that chromophore development only took place when the carbonyl-inactivating sulphite had been removed to some other site where it was more strongly bound. The αβ unsaturated carbonyl compounds examined are themselves not coloured, and the product of a combination between a single amino-group and a straight-chain mono unsaturated aldehyde will still be colourless, as postulated[6] on bathochromic considerations. It seems clear that the initial chromophore development with carbonyl or potential carbonyl compounds may proceed in one of two ways.

The first is the possible development of an ene-dione or diene-al type due to unsaturation being produced

Table 1 COLOUR DEVELOPMENT IN GLUCOSE/GLYCINE MIXTURES WITH ADDED ALDEHYDE*

	3 hours	20 hours	4 days	8 days	18 days
Butyraldehyde	slight pink	vv pale straw	vv pale straw	straw	brown
Crotonaldehyde	v. light brown	golden brown	red brown	deep red brown	red brown
2 ethyl hexanal	—	—	—	straw	brown
2 ethyl-2-hexenal	—	—	v. pale straw	straw	brown
Caproic aldehyde	—	—	—	straw	brown
2 hexenal	pale straw	golden yellow	light brown	brown	dark brown
Glucose/glycine control	—	—	pale straw	yellow	light brown

* 0·1 m.mole of aldehyde incubated with 100 mg glycine and 100 mg glucose in 1 ml. water + 2 ml. ethanol at 50° C.

in the hydroxylic sugar chain followed by cyclization or aldolization. This may explain the initial light yellow coloration often observed; with ensuing polymerization of the unsaturated and carbonyl compounds, more absorptive chromophores will be produced. In the presence of a nitrogen function the reactive carbonyl compounds which develop, often themselves lightly coloured, will combine with the nitrogen function to give more absorptive derivatives, probably cyclic in nature. Evidence exists for the presence of cyclic nitrogen units in water-soluble browning polymers from aldose/glycine systems[7,8] and they apparently form in drying oils[9].

The second is that the initial combination of the nitrogen function with the potential carbonyl group leads, itself, to the development in the sugar chain of unsaturation which is at first conjugated with the C–N link and which may then be followed by: (1) cyclization to give pyrrolic or pyridinic ring compounds which may be self-coloured or which are capable of polymerization; or (2) the conjugated unsaturated carbonyl compound splitting off and engaging in (*a*) cyclization and self-polymerization to develop chromophores or (*b*) reaction with further nitrogen functions to give probably cyclic chromophores which are capable of further polymerization to darker compounds.

There are indications in our work for all these types of reaction since chromophore development can occur under a variety of conditions (for example, *p*H and availability of nitrogen). Many of the reactants (that is, the carbonyl compounds isolated from a glucose/glycine system) give a slow development of chromophores in the absence of a nitrogen function, but a rapid development in its presence.

Where small carbonyl compounds appear to cause browning it would seem that the chromophore development must occur as a result of combinations of the type mentioned at some stage.

In a previous publication[6] we found that heavy sulphiting prevented the appearance of conjugated unsaturated carbonyl compounds in the system and prevented chromophore development. From theoretical considerations one would expect the sulphonyl group to attach to the β-carbon atom and in this position it is clearly a block to αβ unsaturated carbonyl-*N* type chromophore development. The development of αβ unsaturated carbonyls in many foods is thus probably a first step in chromophore development.

Sulphites and Carbonyl-Amino Chromophore Development

The development of carbonyl compounds in systems undergoing non-enzymatic browning has been reported by many workers. In the course of our investigations in this field we came to the conclusion that conjugated unsaturated carbonyl compounds were important intermediates in the development of chromophores in some pathways to melanoidin formation, and that sulphites might form very stable addition compounds at some unsaturated centres[1,6,10].

It is known that αβ unsaturated carbonyl compounds can react with sulphites both at the double bond and at the carbonyl group, but Dodge[5] seemed to be of the opinion that the αβ sulphonyl group could be readily hydrolysed, at least under mild alkaline conditions, and suggested that it might readily migrate.

We have confirmed that sulphite addition to olefinic bonds can occur under mild experimental conditions, but have found that the addition of sodium metabisulphite at the olefinic bond of crotonaldehyde is not reversible under the acidic-hydrolytic conditions of the Monier–Williams determination[11] of sulphur dioxide.

The preceding communication describes the chromophoric development occurring with a number of saturated and unsaturated carbonyl compounds. A similar group of carbonyl compounds comprising crotonaldehyde, mesityl oxide, 2 ethyl-2-hexenal and their saturated analogues were converted into bisulphite compounds. The normal carbonyl bisulphite compounds were prepared by dropwise addition of the carbonyl compound to an excess of an ice-cold saturated solution of sodium bisulphite. The crystalline bisulphite compounds were recrystallized rapidly from aqueous ethanol. The 'abnormal' sulphonated bisulphite compounds of the unsaturated carbonyls, in which addition had occurred both at the olefinic and at the carbonyl groupings, were prepared by stirring and warming the unsaturated carbonyls with an excess of sodium bisulphite solution for 30 min at 60° C. The bisulphite compounds were obtained on cooling as a mass of waxy crystals, and were recrystallized with difficulty from aqueous ethanol.

Consideration of possible reaction mechanisms leads to the conclusion that one of the sulphonic acid groups will be attached to the β-carbon atom, and this conclusion, which had been reached much earlier[12]. is supported by the recent work of Finch[13] on bisulphite addition to acrolein. Unsaturated fatty acids readily give sulphonates; when the double bond is αβ, sulphonic acids are always produced, thus crotonic acid gives β sulphobutyric[14] acid. In the unsaturated ketone series it has been found that most unsaturated ketones will add sodium bisulphite[15–18] in contrast to their saturated analogues.

Confirmation that the olefinic double bond is not readily attacked by bisulphite in the cold but is attacked at 60° C is provided by the fact that only the bisulphite compounds prepared in the cold from unsaturated carbonyl compounds retained the property of rapidly decolorizing bromine water. An investigation was carried out into the hydrolysis of the bisulphite compounds of crotonaldehyde (which analysed for approximately one and two molar additions of sodium bisulphite respectively) under the conditions of the Monier-Williams determination of sulphur dioxide content. The normal aldehyde bisulphite compound gave 90–92 per cent of the calculated quantity of sulphur dioxide. The 'abnormal' bisulphite compound (C_4H_6O, $2NaHSO_3.H_2O$) released only 45 per cent of the calculated amount of sulphur dioxide, showing that one molecule of $NaHSO_3$ was not released on acid hydrolysis. Under the same conditions glucose hydroxy sulphonate (D-glycero-D-ido-hexahydroxy hexyl sulphonate) gave about 97 per cent of the theoretical yield of sulphur dioxide. Mangan and Doak[19] have reported that for foodstuffs the Monier-Williams method often gave inexplicable results, and Williams[20] queried its value as a criterion of the protective powers of sulphite. The former authors suggested that sulphur dioxide was lost by an unidentified reaction which did not require oxygen and yet was responsible for the apparent loss of sulphur dioxide. Hägglund *et al.*[21]

found that heated sugar solutions contained substances which bound sulphite in a non-recoverable manner, and we have shown that in the glucose/glycine systems the appearance of conjugated unsaturated carbonyl compounds is delayed and that the level of these substances can be depressed by heavily sulphiting the system, when the sulphite itself became largely irrecoverable by the Monier-Williams method.

In view of the ease with which the olefinic bond of unsaturated carbonyl compounds is attacked by sulphite it is likely that this mode of combination can account for some of the sulphite loss (as determined by the Monier-Williams method) observed on storing sulphited foodstuffs at temperate and tropical temperatures.

EFFECT OF DEHYDROEPIANDROSTERONE AND Δ^4-ANDROSTENEDIONE ON THE REPRODUCTIVE ORGANS OF FEMALE RATS: PRODUCTION OF CYSTIC CHANGES IN THE OVARY

By SOMNATH ROY*, VIRENDRA B. MAHESH and ROBERT B. GREENBLATT

Medical College of Georgia, Augusta, Georgia

RECENT work has shown that the polycystic ovaries of Stein–Leventhal syndrome contain and secrete abnormal quantities of androgens such as dehydroepiandrosterone (DHA) and Δ^4-androstenedione[1-3]. These are relatively weak androgens, and when administered intravenously to rats[4] or perfused through the liver of dogs[5] are partly converted to testosterone. Mahesh and Greenblatt[6] have administered orally the foregoing two steroids to normal women and found elevated levels of plasma testosterone. These observations may serve to explain the frequent occurrence of hirsutism in the polycystic ovary syndrome.

The other manifestations of this syndrome are absent or infrequent ovulation, amenorrhœa, sterility, and microcystic changes in the ovary. Although various theories have been proposed to explain the pathogenesis of this syndrome, considerable gaps in our knowledge remain. Many steroids are known to influence the physiology of reproduction in variable degrees[7]. However, no attention has hitherto been paid to the role of the aforementioned androgens in the pathogenesis of the polycystic ovary syndrome. This is especially pertinent because testosterone has been shown to cause anovulation and cystic changes in the ovary in mice[8] and rats[9] if given in early neonatal life. Therefore it seemed of interest to study the effect of DHA and Δ^4-androstenedione on the reproductive organs of young female rats, and to ascertain whether cystic changes in the ovary can be induced.

Forty-two female Sprague–Dawley rats, 22–23 days old and weighing 42·3 ± 3·2 g were divided into 7 groups of 6 each. One group was kept as normal controls. Six other groups were treated with graded doses (0·1, 0·3, 1, 3, 10, and 30 mg/kg body-weight) of DHA in 0·2 c.c. of corn oil given subcutaneously for 36 days. Another batch of 42 female rats of the same age and weighing 43·9 ± 2·8 g were similarly divided and treated with identical graded doses of Δ^4-androstenedione. The control rats received the injections of 0·2 c.c. of oil alone.

The animals were kept under uniform husbandry conditions and were killed on the day following the last injection. They were anæsthetized with intraperitoneal injections of 'Nembutal', and the blood was drawn from the abdominal aorta. The ovaries, uteri, adrenals and pituitaries were dissected out carefully and weighed on a precision balance. The plasma was processed for steroid fractionation studies and the pituitaries for the determination of their luteinizing (LH) and follicle-stimulating hormone (FSH) contents. The other organs were fixed in 10 per cent formalin for histological studies.

The results of the studies with DHA and Δ^4-androstenedione are presented in Tables 1 and 2 respectively. The greater gain in the body-weight of the animals in the steroid-treated groups is probably due to the anabolic action of the test compounds. In DHA-treated animals the relative weight of the ovary showed a progressive decrease with doses 0·3 mg and greater, whereas such a decline in ovarian weight was noted with only 10- and 30-mg doses of Δ^4-androstenedione. This is caused presumably by inhibition of pituitary gonadotropin secretion. It may be assumed that by the same action these steroids will also be able to inhibit ovulation. However, it is well to mention the fact that Nelson and Patanelli[10] pointed out it is probably not essential that complete or even marked inhibition of gonado-

tropin be produced by the various steroids to prevent ovulation. It is required only that the FSH/LH ratio be disturbed to a degree that follicular maturation and rupture do not progress normally. On this basis it may be postulated that such inhibition of ovulation will be possible by DHA and Δ^4-androstenedione, which have been shown to be converted into testosterone in the body.

At the dosage of 10 and 30 mg, both the compounds produced cystic changes in the ovaries of most of the animals and at 3-mg dose only a few ovaries showed such change. They were very easily noted under a magnifying glass and were filled or distended with clear fluid. None of the control animals showed any cysts in its ovaries on macroscopic examination. This change may be due to a direct effect of the steroids on the ovary or to modification of gonadotropin action or to a change in the sensitivity of the ovary or to a combination of two or more of these factors.

At the higher dosage-levels these steroids increased the weight of the uterus. Such action of DHA was manifested only with the 30-mg dose, whereas the uterotrophic effect of Δ^4-androstenedione was overt with 1 mg and more. It is worthy of note that there was an increase in the absolute and relative weights of the uterus in spite of a marked decrease in the ovarian weight when larger doses of steroids were administered. Some of the uteri were distended with fluid in their lumen. It is not known whether the uterotrophic action of these steroids is due to a direct effect or to their conversion into testosterone or œstrogen.

A significant decrease in the relative weights of the adrenals was noted at 30-mg dose-level of both the steroids and also at 10-mg dose of Δ^4-androstenedione. This may be caused by inhibition of secretion of adrenocorticotrophic hormone from the pituitary.

Based on the recent observations[2,3] and on the findings of the present study, a tentative hypothesis for the pathogenesis of the polycystic ovary syndrome of Stein–Leventhal may be suggested. In such ovaries, due to the enzymatic abnormalities, œstrogen biosynthesis is partially blocked. As a result there occurs a relative lack of œstrogen in the body which probably causes increased secretion of pituitary gonadotropin, primarily FSH. At this stage the ovaries may become enlarged by the stimulation of excess gonadotropin. In an attempt to produce physiological amounts of œstrogen such ovaries produce large quantities of androgens like DHA and Δ^4-androstenedione. Now the high level of circulating abnormal androgens may act on the pituitary and suppress the already elevated gonadotropin secretion to some extent. But the more important effect probably is that they may modify the FSH/LH ratio in such a way as to inhibit ovulation and thus expose the ovaries to a continuous and a preponderance of FSH stimulation. Added to these, the androgens probably modify the response of the ovaries to gonadotropin, leading to polycystic changes in the ovary.

It is not known whether there is any enzymatic defect in the ovarian hormone synthesis in patients with adrenogenital syndrome. However, in the light of the observations of the present study, the occurrence of polycystic ovaries in patients with adrenogenital syndrome may probably be explained on the basis of high level of adrenal androgens circulating in the blood.

Investigations in animals as well as in human beings are in progress for further elucidation of the problem. The results will confirm, extend or modify the above hypothesis.

LACTOSE FERMENTATION BY *SHIGELLA SONNEI*

By PROF. MITSURU NAKAMURA and CARLA R. CLAUSEN*

Department of Botany and Microbiology, Montana State University, Missoula

IN 1919 Thjelta[1] reported that *Shigella sonnei* colonies turned red on lactose agar after 48 h of incubation. Nelson[2] reported that this organism produced acid without gas in laxtose broth by the third day and sometimes not until the seventh day. Sears and Schoolnik[3] found that slow lactose-fermenting *S. sonnei* fermented lactose rapidly after being transferred several times in lactose broth. Hershey and Bronfenbrenner[4] stated that it was possible to induce rapid lactose fermentation by various manipulations. According to Glynn and Starkey[5] the lactose-positive papillæ of *S. sonnei* did not breed true. They found that each time the secondary papillæ were replated, the colonies started as a lactose-negative colony and formed the lactose positive papillæ only on continued incubation. Neter[6] felt that the appearance of these papillæ on prolonged incubation was due to fermentation of lactose at a later time rather than to the slow utilization of the carbohydrate. It has been reported that *S. sonnei* can be 'trained' to ferment lactose more rapidly by cultivation in lactose media[3]. Cook *et al.*[7] believed that the speed of lactose fermentation depended on the proportion of lactose-fermenting mutants present. The percentage of mutant cells is dependent on rate of mutation, relative growth-rates of normal and mutant cells, and possible inhibitory effect of normal cells on growth or adaptation of the mutant. Late fermentation may be due to the time interval necessary for the mutants to establish themselves in culture in sufficient numbers to produce the detectable effects. Mundt and Hitchner[8] were not able to increase or decrease the rate of lactose fermentation by various manipulations. Kacoyanis and Baker[9] reported that one-third of a culture of *S. sonnei* was lactose-positive after holding for 10 days in lactose broth. The lactose-fermenting mutants were stable and retained their ability to ferment lactose within 48 h even after 30 sub-cultures in media not containing lactose.

The ability of *S. sonnei* to ferment lactose is of diagnostic importance. Since this organism ferments lactose slowly (several days to several weeks) we thought that reliable methods for accelerating this diagnostic reaction would be of clinical importance. This investigation deals with the study of various factors which affect the lactose-fermenting ability of *S. sonnei*.

Three strains of *S. sonnei* used in this work were obtained from Commander T. M. Floyd, Naval Medical Center, Bethesda, Maryland. Three strains of *S. sonnei* were received from Dr. Maxwell Finland, Boston City Hospital, Boston, Massachusetts. One strain was obtained from Dr. Arthur Abrams, Walter Reed Army Hospital, Washington, D.C., and a strain was received from Dr. H. M. Gezon, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania. *Shigella dysenteriae* 1, *S. boydii* 1, *S. flexneri* 2*a*, and strain 01 of the Alkalescens-Dispar group (Edwards and Ewing[10]) were supplied us by Dr. W. H. Ewing, Laboratory Branch, Communicable Disease Center, Atlanta, Georgia. The culture of *Escherichia coli* used in this work was purchased from the American Type Culture Collection, Washington, D.C. The organisms were grown on nutrient broth (Difco), nutrient agar (Difco), and the chemically defined medium of Erlandson and Mackey[11]. Lactose fermentation broth was prepared by adding 5 g/1,000 ml. of lactose in nutrient broth and 0·1 per cent bromthymol blue (Baltimore Biological Laboratory, Baltimore, Maryland) as the *p*H indicator. This indicator was blue at a *p*H of 7·6 or higher and turned yellow at a *p*H of 6·0 or lower. A 1 per cent concentration of fructose, mannose, glycerol, maltose, and lactose was used in place of glucose in the chemically defined medium during certain phases of this work. The media were prepared in distilled, de-ionized water ('Crystalab Deeminizer', Crystal Research Laboratories, Inc., Hartford, Connecticut), adjusted to *p*H of 7·0, and autoclaved at 15 lb. of pressure for 15 min. The sugars were sterilized by Seitz filtration and added aseptically to the sterile media. Eosin methylene blue (EMB) agar (Difco) plates were used to determine the number of lactose-fermenting colonies.

Stock cultures of the organisms kept as reference cultures were grown for 24 h on nutrient agar slants and then retained in the frozen state (−20° C). The cultures were checked periodically for purity by biochemical, serological and morphological methods. The size of the inocula was determined prior to inoculation into lactose fermentation tubes. This was done by making an appropriate number of serial

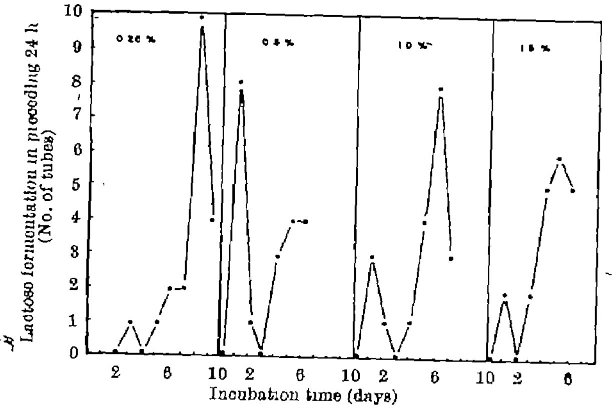

Fig. 3. A comparison of lactose fermentation times of *S. sonnei* grown in various concentrations of lactose

dilutions and streaking 0·1 ml. of the final dilution over a nutrient agar plate and streaking with a bent glass-rod 'hockey stick'. The plates were inverted and incubated for 24 h at 37° C and the colonies were counted with the aid of the Quebec darkfield colony counter (Spencer). Cell suspensions were similarly grown on EMB agar to determine the percentage of lactose-fermenting colonies. The plates were daily for 7 days.

In order to determine the lactose fermentation time, the lactose fermentation broth was dispensed into test tubes (16 × 100 mm); 5 ml. of the broth were placed into each test tube. Each experiment was performed with 20 tubes. The cells used for inocula were transferred daily for 5 days and suspended in sterile distilled water to yield a count of 1·0–1·5 × 10^8 cells per ml. The fermentation tubes were inoculated with 0·1 ml. of this cell suspension and examined visually daily for acid production. The appearance of the yellow colour indicative of acid production was sometimes so gradual that it became necessary to compare the tubes with a definitely positive reaction produced by a 24-h culture of *E. coli*. The number of tubes that became positive each day was recorded, and tabulated. Admittedly there was a degree of subjectivity in our method of recording lactose fermentation. Later we read the tubes in the Bausch and Lomb 'Spectronic 20' spectrophotometer as an aid to supplement our visual observations. The tubes were held until they had all produced the acid reaction. During certain phases of our work the volume of the lactose fermentation broth was varied.

We also investigated the effect of ultra-violet light on the ability of *S. sonnei* to ferment lactose. A General Electric Co. 15-W 'germicidal' lamp (*G15T8*) with an approximate wave-length of 2,537 Å was used. The calculated dose was 17·2 ergs/sec/mm². The cells were irradiated for 1, 5, and 10 min. Immediately after irradiation aluminium foil was placed over the dishes to minimize the possibilities of photoreactivation. The irradiated cells were grown for 3 days (transferred daily) and then assayed for their lactose-fermenting abilities. Unirradiated cells, similarly treated, served as controls. Various inducers were also studied to determine their activities in accelerating lactose fermentation times.

The average lactose fermentation times of the 8 strains of *S. sonnei* tested are shown in Fig. 1. The data are averages obtained from 20 tubes. Except for one strain (*B*–2569–2) the other strains produced an acid reaction in lactose broth in 4½–5½ days. *E. coli* fermented lactose in less than 24 h. None of the other species of *Shigella* fermented lactose during the 20 days these tubes were held for observation. There was no appreciable change in the lactose fermentation times when the volume of the lactose fermentation broth was increased from 5 to 10 ml. On EMB agar there were no detectable pink colonies of *S. sonnei* after 24 h of incubation for any of the 8 strains tested. However, after 48–72 h of incubation lactose-positive colonies appeared on the EMB agar. The percentage of positive colonies ranged from 11 to 57 per cent (of all the visible colonies) after 48 h and from 44 to 81 per cent after 72 h of incubation. The results are given in Table 1. It is interesting to note that there was a considerable variation in the percentage of lactose-positive colonies whereas there was only a slight variation from strain to strain when the lactose-fermenting ability was tested in broth.

S. sonnei was grown in 0·5 per cent lactose to determine its effects on the lactose fermentation times. As can be seen in Fig. 2 there was a marked acceleration in the time necessary for the fermentation of lactose. The largest number of lactose-positive tubes appeared on the first day and the average fermentation time was 3·3 days compared with 5·3 days for organisms not grown on lactose (a composite

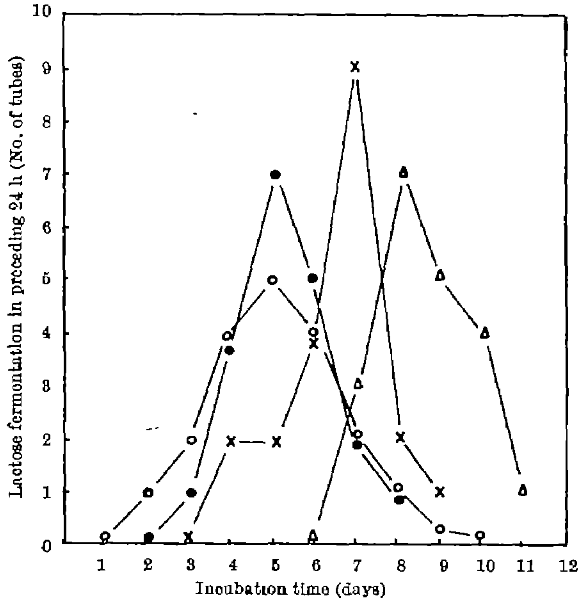

Fig. 5. The average lactose fermentation times of *S. sonnei* irradiated with ultra-violet light for 1 min (×), 5 min (●), and 10 min (Δ), compared with unirradiated (○) controls

of the 8 strains). Other concentrations of lactose were tested as inducers of lactose fermentation. The data are summarized in Fig. 3. Growth of *S. sonnei* in 0·25 per cent produced the slowest lactose fermentation time (average of 7·5 days); growth in 1·0 and 1·5 per cent lactose resulted in average fermentation times of 4·9 and 4·4 days, respectively. The shortest lactose fermentation time was produced by growth in 0·5 per cent lactose. There appears to be an optimal concentration of lactose which accelerates the lactose fermentation of the cells.

S. sonnei was grown in the presence of galactose to discover if galactose could stimulate the lactose fermentation of this organism. The results are summarized in Table 2. The time necessary for lactose fermentation did not vary much when the organisms were grown in 0·1–1·0 per cent galactose. As a matter of fact the lactose fermentation times following growth in galactose were larger than the organisms grown in the absence of galactose. This suggests that growth in galactose produced an inhibition in the ability of the *Shigella* to ferment lactose. Figure 4 shows the relationship between the lactose fermentation time of organisms grown in the presence of galactose compared with organisms grown in the absence of galactose. The average lactose fermentation time of *S. sonnei* following growth in 0·5 per cent α-melibiose was 7·3 days. Melibiose also produced a slight inhibition of the ability of this organism to ferment lactose.

Fig. 5 shows the effect of ultra-violet irradiation on the ability of *S. sonnei* to produce lactose fermentation. The lactose fermentation times of cells irradiated for 1 and 10 min were increased whereas the lactose fermentation time of cells irradiated for 5 min was similar to the unirradiated controls. After 1 min of irradiation the average fermentation time was 6·5 days; after 10 min of irradiation the average fermentation time was increased to 8·7 days. Unirradiated cells and cells irradiated for 5 min produced average fermentation times of 5·3 days. An adequate explanation is not available for the inhibition in fermentation produced by 1 min irradiation when 5 min of irradiation had essentially no inhibitory effect.

The fermentation of lactose by *S. sonnei* is an extremely variable property. Glynn and Starkey[5] reported that it took a broth culture 2–32 days to ferment lactose. On the other hand, utilizing large numbers of tubes, we have found that the average lactose fermentation times are rather consistent. It seems that the number of fermentation tubes used in a given experiment is an important variable. Variations in the average fermentation times between strains of *S. sonnei* appeared to be only slight. Glynn and Starkey[5] suggested that the time required for lactose positive colonies to appear on lactose agar could be roughly correlated with the time required for the organism to ferment lactose in a broth medium. We have found that lactose-positive colonies appeared on EMB agar within 2–3 days whereas the average lactose fermentation time was about 5 days. We feel that it is unreliable to determine lactose fermentation in *S. sonnei* by the inoculation of one or several tubes since variations in individual tubes are great even when the tubes have been inoculated from the same original culture. We have found that growth of *S. sonnei* in lactose increase the rapidity of lactose fermentation by this organism. This is in agreement with many other workers[12,13].

ZONE PRECIPITATION

By Dr. JERKER PORATH

Institute of Biochemistry, University of Uppsala

N preparative and analytical biochemistry precipitation and crystallization have been largely uperseded by more sophisticated procedures such as ounter-current extraction, zone electrophoresis and arious kinds of chromatography. Solubility is a owerful 'separation parameter' that deserves to be tilized also when efficient fractionation is attempted. t is the purpose of this article to describe a column rocedure based on precipitation-dissolution proesses.

Suppose a precipitating agent moves in a sorbent ed with a slower speed than the substances to be recipitated. If adsorption or molecular sieving do ot affect the latter, solubility would be the only actor to cause their differential migration. Such onditions prevail, for example, when proteins move n beds of particulate, highly cross-linked dextran[1] n which the concentration of ammonium sulphate gradually increases from the top downwards.

If a protein is filtered through such a column it moves faster than the ammonium sulphate, and a region is reached where precipitation occurs. Clearly the critical concentration of ammonium sulphate for formation of a precipitate depends on the nature and concentration of the protein. When the particles have grown to a certain size their migration ceases. As the solvent passes the precipitate will soon be back in an unsaturated environment. Dissolution starts and the substance moves again. These events are presumably repeated to yield a continuous migration of a solute-precipitate containing zone. When a protein mixture is passed through the bed the components will precipitate in different parts of the column according to their relative solubilities. The zones thus formed move through the column and the substances appear separated in the eluate. The principle is schematically illustrated in Fig. 1.

The separation efficiency may be reduced by the fact that the crystals or particles have to grow large until they are entrapped in the bed. The choice of the gel in the present investigation has been made on the assumption that a limited penetrability of the proteins may be advantageous, since nuclei will then be formed in the gel phase where extensive growth is impossible.

The term 'zone precipitation' is tentatively suggested for the method, which is not limited to gel filtration only.

Some exploratory experiments have been made, two of which are described here. They were performed under primitive conditions since adequate instruments were not available either for the production of a continuous linear gradient or for convenient recording of the ammonium sulphate concentration in the effluent. Gradients covering intervals of 25–35 per cent saturated ammonium sulphate solution seem to give the best results. Extraction has been made with decreasing ammonium sulphate, but this act does not appear to have affected the fractionaion to any extent.

(1) Human serum was fractionated on a 'Sephadex G200' column as described by Flodin and Killander[2]. A fraction corresponding to the substances present in peak 3 and the rear part of peak 2 was concentrated to one-fourth of the original volume of the serum.

A chromatographic column tube (3·5 × 40 cm) closed at the bottom with a porous plate[3] was filled with a suspension of the dextran gel 'Sephadex G100' (140–200 mesh, obtainable from Pharmacia, Uppsala, Sweden) in a solution of 85 per cent saturated ammonium sulphate containing 0·5 M tris-hydroxy-methylamino-methane and adjusted to pH 8·8. The 'Sephadex' particles were allowed to settle. A bed 33 cm high was obtained. The solution above the sediment was removed. Five millilitre portions of ammonium sulphate–buffer solution were washed into the bed in a sequential manner to produce a stepwise gradient from 85 to 55 per cent saturated ammonium sulphate solution. Three millilitres of the serum fraction were washed into the column followed by ammonium sulphate–buffer solution. The ammonium sulphate concentration was continuously lowered from 55 to about 20 per cent saturated ammonium sulphate solution.

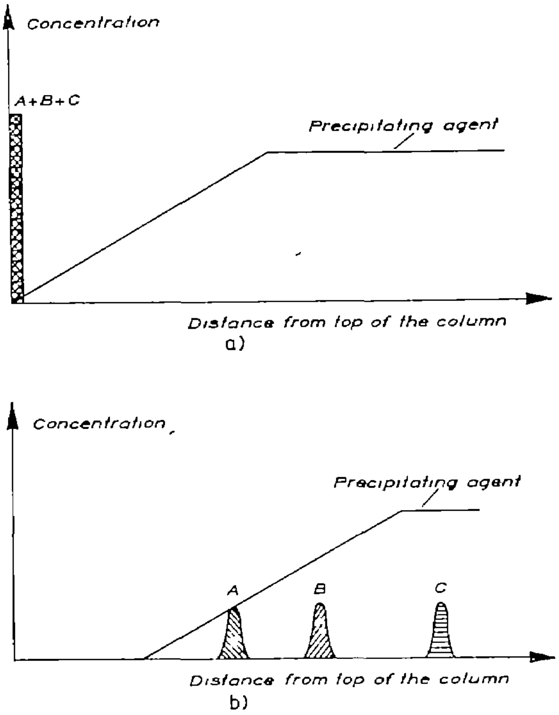

Fig. 1. The principle of zone precipitation exemplified for three substances A, B and C of different solubilities. a, Starting conditions; b, in the first phase of washing the substances A, B, C all move faster than the gradient substance. After reaching the gradient they display different behaviour C moves independent of the gradient, A and B are retarded to different extents

The eluate was collected in 3·5-ml. fractions, the ultra-violet absorption of which were measured at 280 mμ. Fig. 2 shows the material distribution. The last peak contained material precipitated on top of the column and later dissolved in the eluent. Fractions were pooled as indicated in the diagram, concentrated and subjected to electrophoresis on paper and in polyacrylamide. The results of the paper electrophoresis experiments are shown in Fig. 3. Peak 1 contained albumin, ferritin and some α_1-globulin. In peak 2, α_1, α_2, β and fast-globulin were found to be present together with small amounts of albumin. Peak 3 contained two globulin components which were clearly separated by paper electrophoresis. Only traces of faster components were found in this fraction.

(2) α-Hydroxysteroid dehydrogenase of *Pseudomonas testosteroni*[5] was purified by ammonium sulphate precipitation followed by gel filtration on 'Sephadex *G*100' (ref. 6). The activity was collected and concentrated. Three millilitres of concentrated solution were applied to a column prepared as described in experiment 1. Elution was also performed in the same manner. The enzyme activity was determined as previously described. The distribution of ultra-violet absorbing material and activity is shown in Fig. 4; it strikingly resembles a good elution chromatogram in the sharpness of the enzyme zone.

Instead of a stepwise gradient as used in these experiments, continuous smooth change in concentration of the ammonium sulphate should be preferred, particularly in cases where zone precipitation is used to test homogeneity of protein preparations.

Capacity, optimal rate of development and bead size are largely unknown factors. In a series of experiments on a certain column it was found that similar distribution patterns were obtained for loads of 0·5–3 ml. serum; 5 ml. was too high a load.

Clogging of the beds has never been observed as a result of precipitation within a column, but a heavy precipitate formed at the top may cause distortion of the zones.

Large bed volume changes seriously affect the packing and the flow rate. The swelling of 'Sephadex *G*100' and '*G*200' are very slightly affected by the ammonium sulphate but a volume expansion as great as 20–25 per cent has been noticed occasionally for 'Sephadex *G*25'.

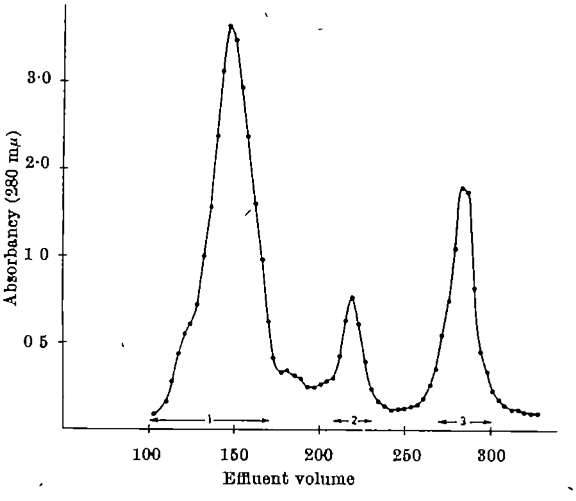

Fig 2 Zone precipitation diagram of a serum fraction. A step gradient of ammonium sulphate from 85 to 55 per cent saturation was used

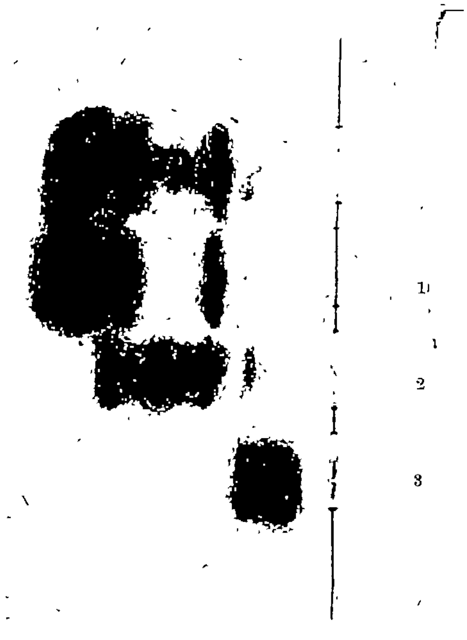

Fig. 3. Paper electropherograms of starting material and Fractions 1, 2 and 3 referred to in Fig. 2 Buffer according to Aronsson-Gronwall (ref. 4), pH 8·9; Whatman No. 1 paper; 5–6 m.amp, 225 V; 24 h. Paper stained with bromophenol blue

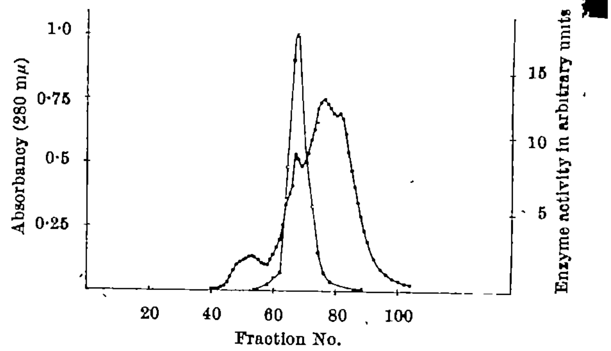

Fig. 4. Zone precipitating diagram of a α-hydroxysteroid dehydrogenase preparation. Gradient, 85–55 per cent saturation of ammonium sulphate

Beside its value as a purification method, zone precipitation may also be of great help in finding suitable conditions for crystal formation. This may be a very important application in view of the increasing importance of X-ray analysis in elucidation of protein structures.

In this presentation of the zone precipitation method its usefulness for protein fractionation may have been overemphasized. Very likely it will be rewarding to explore its potentialities in other fields.

This investigation has been financially supported by a grant from the Swedish Natural Science Research Council.

A CHALLENGE TO THE CONCEPT OF SELECTION BY MALARIA IN GLUCOSE-6-PHOSPHATE DEHYDROGENASE DEFICIENCY

By DR. CHEV KIDSON
Baker Medical Research Institute, Melbourne, Australia*
AND
DR. J. G. GORMAN
Department of Pathology, College of Physicians and Surgeons, Columbia University, New York

IN considerations of polymorphisms in man, a pre-eminent role has frequently been invoked for infectious diseases, and in this regard malaria has featured prominently. Increased resistance to *Plasmodium falciparum* infection was shown by Allison[1] in 1954 to be conveyed by the sickle-cell trait, and it has been concluded[2] on the basis of cumulative evidence from many investigators that *falciparum* malaria appears to act as a selective pressure favouring the heterozygote carriers, with consequent high frequency for the sickle-cell gene in areas holoendemic for this form of malaria.

Fewer critical studies have been performed for thalassæmia, although the geographical distribution of the trait follows that of *Pl. falciparum*[3]. Ceppellini[4] has shown, however, that there is a much higher incidence of thalassæmia in malarious regions of Sardinia than in non-malarious regions of the island, and similar demography has been observed in New Guinea (Curtain, Kidson, Gorman and Gajdusek, unpublished work). Similarly, the geographical distribution pattern of glucose-6-phosphate dehydrogenase (G6PD) deficiency has suggested a relationship to malaria[5,6]. Investigations in Africa[5,7], Melanesia[8,9] and Sardinia[10] have indicated a pattern of varying frequency of the trait which is roughly proportional to varying malarial incidence within a given country. Of equal interest is the apparent absence of the trait in Japanese[6], Eskimos[6] and Australian Aborigines[11], all people occupying non-malarious regions, suggesting that the gene responsible either has never existed in these populations or has failed to survive.

The overall distribution pattern represented by the world map for these genetic conditions—sickle-cell, thalassæmia and G6PD deficiency—has a similarity to the map for *falciparum* malaria, as stressed by Motulsky[6]. It could be argued, however, that very many other parasitic diseases, in addition to variable degrees of nutritional inadequacy, are seen in this same tropical belt, and may be concerned, likewise, as selective pressures influencing the frequency of one or more of these traits. The temptation to implicate malaria alone has been strengthened by consideration of the effects of these particular mutant conditions on the physiology of the human erythrocyte—especially understandable in the case of G6PD deficiency[12]—which provides the essential biochemical environment for malarial parasite life and reproduction. The demonstration by Allison and Clyde[13] that *Pl. falciparum* parasite-rates and densities were lower in young African children with G6PD deficiency than in children with normal enzyme-levels has appeared to lend further emphasis to the probability that G6PD deficiency conveys increased resistance to *falciparum* malaria, making the trait common in malarious areas.

Examination of the world distribution in detail, however, shows some important exceptions to the apparent rule of correlation of high malarial endemicity with high incidence of G6PD deficiency. Thus, both Malays[14] and Indonesians (Lie-Injo, L.E., personal communication) possess the gene in low frequency although in surrounding populations in some regions of Thailand[15], the Philippines[6] and coastal New Guinea[8] higher frequencies occur. Both Malaya and coastal Indonesia are highly malarious areas and the Malay peoples have been resident there for about 4,000 years, a time-period sufficient for the gene to build up to higher levels under selective pressure from *falciparum* malaria. Armenians are another population who have inhabited a malarious area for a long time period yet have a very low incidence of G6PD deficiency[16].

In a further series of investigations of G6PD deficiency in the Melanesian populations of New Guinea and New Britain[18] it has become evident that a direct correlation of incidence of the trait with endemicity of *falciparum* malaria represents too superficial an appraisal of the question of selection pressures, and that in fact malaria may not even be the major factor involved in this process. New Guinea presents in many ways a rather unique situation for examining human genetic patterns in relation to selective forces, containing as it does several hundred linguistic groups living under very similar environmental conditions, groups which have maintained their separate identity for long periods of time, while possibly coming in the distant past from a common source[17]. Population groups are available for study from sea-level to altitudes above 5,000 ft. All coastal areas of New Guinea and New Britain are holoendemic for malaria—predominantly *falciparum* and *vivax*—while gradations of malarial endemicity are present from the coast to the highlands, the latter possessing little or none of the disease except in occasional epidemic form. Early surveys of this enzyme deficiency in Melanesians[8,9,18], based on examination of randomly collected blood samples sent by air by various field workers in New Guinea to our laboratory in Melbourne, had revealed a general trend showing a very low frequency (< 0·01) of G6PD deficiency in the highlands and a moderately high frequency (> 0·10) in coastal regions. These findings appeared to follow the pattern observed in Africa[5,7] and later noted in Sardinia[10].

---

* Postal address Commercial Road, Prahran S.1, Victoria, Australia

The more recent field examination[19], however, has enabled a detailed investigation of the distribution pattern of the trait among various linguistic groups, with results which throw strong doubt on the theory of malarial selection. Three areas were examined: (1) the Gazelle Peninsula, New Britain, less than 500 ft. altitude; (2) the Sepik River district, New Guinea, less than 500 ft. altitude; (3) the Markham River valley, near Lae on the east coast of New Guinea, from sea-level to the Eastern Highlands, with an altitude of more than 5,000 ft. G6PD activity of red blood cells was estimated semi-quantitatively in the field by a rapid modification[20] of the dye decoloration test[21] and confirmed by quantitative assay[22] on blood samples sent by air to the laboratory in Melbourne.

In Table 1 are shown the results for the gene frequency in males in linguistic groups of the Gazelle Peninsula in New Britain and the Sepik River district of New Guinea. The difference between the Tolai linguistic group and the Sulka and Baining groups in the Gazelle Peninsula is striking, the latter having a much higher incidence than the Tolai ($P < 0{\cdot}01$). A similar, though less striking, difference is seen between the Abelam and Sause groups in the Sepik River district ($P < 0{\cdot}01$). In each area the various linguistic groups examined live under similar conditions of nutrition and of parasitic infestation, although those in the Gazelle Peninsula inhabit a much more fertile region and probably enjoy a more adequate diet than those in the Sepik River district. *Falciparum* malaria is holoendemic in both regions. Thus, we find the phenomenon of culturally distinct population groups living in close proximity, both possessing the mutant gene for G6PD deficiency, yet exhibiting extreme differences in frequency of that gene under conditions where it might be expected that malaria would exert an equal selection pressure for G6PD deficiency on both groups. It is possible, of course, that the gene has spread only recently to the Tolai and Sause; but it is significant that among the latter, at least, the gene is scattered among many villages and the incidence does not reflect a single family breeding group. This argues against random drift, and suggests that the gene has been present in these population groups for some time but either has not reached high proportions due to favourable selective pressure or has been kept at low levels by adverse forces.

Table 1. GENE FREQUENCIES FOR G6PD DEFICIENCY IN THE GAZELLE PENINSULA AND THE SEPIK RIVER DISTRICT

Linguistic group	No. examined (males)	Gene frequency (males)
Gazelle Peninsula New Britain		
Tolai	122	0·008
Sulka	102	0·150
Baining	108	0·120
Sepik River District New Guinea		
Sause	324	0·009
Abelam	49	0·080

Findings in the Markham River valley and the Eastern Highlands of New Guinea are summarized in Fig. 1. The apparent gradation in incidence of G6PD deficiency with changing altitude, from high incidence on the coast to low incidence in the highlands, would seem to be readily explained by a parallel influence of malaria, chronic malaria being less frequent among the Mumeng than in the Wampur and Bukawa groups, and rare in the highlands peoples. However, it is equally possible that this pattern may in fact be the result of spread from a large gene pool on the coast near the river mouth, with dilution and diminution of the gene frequency along the valley towards the highlands, and evidence accumulating from studies of other genetic parameters (Curtain, Gorman and Kidson, unpublished) suggests that this may indeed be so.

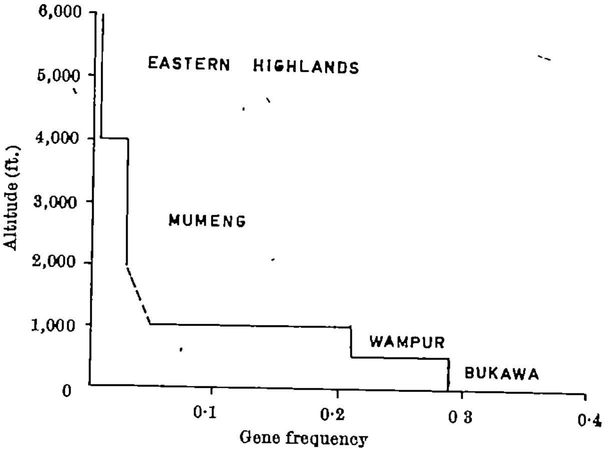

Fig. 1. Variation of gene frequency for G6PD deficiency with altitude in linguistic groups in the Markham River valley and in the Eastern Highlands

The gene frequencies for G6PD deficiency in several linguistic groups studied in the Eastern Highlands are shown in Table 2, to demonstrate their distribution. While the overall incidence is low, the frequency in some linguistic groups such as the Auyana may reach or exceed that in some coastal groups.

Table 2. GENE FREQUENCIES FOR G6PD DEFICIENCY IN THE EASTERN HIGHLANDS

Linguistic group	No. examined (males)	Gene frequency (males)
Tairora	88	0·011
Gadsup	89	0·000
Auyana	40	0·050
Kukukuku	116	0·000
Fore	39	0·000

Comparison of the demography in New Guinea and New Britain of G6PD deficiency and thalassæmia has revealed a dissociation between the distribution patterns of these two genetic traits. Thus, while G6PD deficiency shows the above erratic frequencies in the linguistic groups examined, thalassæmia shows a consistent incidence of 4–7 per cent in all groups in coastal regions, rapidly diminishing as altitude rises above 1,000 ft. (Curtain, Kidson, Gorman and Gajdusek, unpublished). This dissociation strongly suggests that different selective forces operate for the two conditions.

Assessment of parasite-rates and densities in the populations investigated here have proved completely unreliable because of the spasmodic administration of antimalarial drugs at uncertain time intervals. Wilson[23] has pointed out that Allison and Clyde's[13] finding of differences in parasite densities between African children with low enzyme-levels and those with normal levels does not provide evidence of protection from the lethal effects of *falciparum* malaria. Moreover, the recent report of Kruatachue and Harinasuta[15] suggests that no significant difference in *Pl. falciparum* parasite densities occurs between affected and normal children under 3 years of age in Thailand and that affected children in this age group may have higher densities of the non-lethal *Pl. vivax*. It is doubtful, therefore, whether satisfactory evidence is available from this source to assist in the evaluation of the part played by *falciparum* malaria in selection for this gene.

It is possible that selection factors may act rather differently in different population groups. That G6PD deficiency may in fact represent a common end-product of multiple underlying genetic mechanisms was first suggested by Marks and Gross[24], who pointed out the quantitative differences between affected Negroes and affected Caucasians, and was strengthened by the subsequent findings of different tissue distribution of enzyme deficiency in these two groups[25,26]. Primary deficiency of an activator of G6PD was recently reported in Sephardic Jews in Israel by Rimon *et al.*[27]; we have found heterogeneity of response to the activation reaction in Melanesians[28], suggesting that multiple mutations may be involved, and have shown that deficiency of an activator is not the primary defect in enzyme-deficient Negroes[29]. It may well be that selection pressures operate somewhat differently in these differing groups, even though the final result, deficiency of the enzyme, is common to all.

Tempting as it is to correlate the distribution and frequency of *falciparum* malaria with the frequency of a genetic trait such as G6PD deficiency, such a concept must face the contrary evidence of low incidence of the deficiency in large groups such as Malays, Indonesians and Armenians and small groups such as the Tolai and Sause in Melanesia, all of which inhabit holoendemic malarious areas. Although similar conditions of parasitic infestation pertain, it is of course remotely possible that restricted cultural contact between the Melanesian linguistic groups could result in limited epidemics of certain virus diseases, reported in some cases as initiating acute hæmolysis in enzyme-deficient subjects[20], thereby causing differential loss of the mutant gene by death of carriers in affected groups. However, the influence of social factors themselves, as emphasized by Lehmann[31] for sickle-cell disease, must not be forgotten in considerations of G6PD deficiency.

Vastly differing marriage customs are known in many regions in New Guinea, some tending to lead to marked inbreeding, others to the contrary; doubtless similar variation exists in other regions such as Africa. Then, too, population pressures have frequently led to small groups being pushed inland from coastal precincts into highland areas, a fact which may explain genetic gradients from coast to highlands in many parts of the world. Geographically limited pockets of rare syndromes such as Kuru bear exotic witness to the not infrequent phenomenon of inbreeding in New Guinea. It is possible that a complex interaction of malaria, viral infections, dietary habits and social customs is involved in producing the present pattern of distribution of G6PD deficiency, with social customs playing a much more dominant part than has been attributed to them in previous considerations of genetic polymorphisms in man.

These investigations were supported in part by grant *H*-6109, appropriation 911–283 of the U.S. Public Health Service.

EFFECT OF THYMIDINE ANALOGUES ON REPRODUCTIVE MORPHOGENESIS IN *ARABIDOPSIS THALIANA* (L.) HEYNH.

By J. A. M. BROWN

Department of Biology, Brookhaven National Laboratory, Upton, New York

RECENT reports have indicated that the inductive dark period processes required for the initiation of floral morphogenesis in short-day plants can be affected by modifications of nucleic acid metabolism. Flowering has been promoted by added RNA nucleosides[1], and inhibited by 5-fluorouracil (FU) and 5-fluorodeoxyuridine (FUDR)[2,3]. In micro-organisms 5-bromodeoxyuridine (BUDR) and 5-iododeoxyuridine (IUDR) have been shown to replace thymidine in the biosynthesis of DNA. As a consequence of such incorporation, mutational changes may occur in subsequent DNA replication[4]. IUDR incorporated into mammalian chromosomes has enhanced radiosensitivity[5]. More recently, the incorporation of

Table 1. EFFECT OF GIBBERELLIC ACID (GA), 5-IODODEOXYURIDINE (IUDR), AND THYMIDINE (Thy.), ON GROWTH

Treatment	No. rosette leaves	No. cauline leaves	Mean stem-height (mm)
Exp. 1: 33 days after sowing	$\bar{x}$ $s_{\bar{x}}$	$\bar{x}$ $s_{\bar{x}}$	
Control	11·3 ± 0·2	0	0
GA	9·6 ± 0·2	3·23 ± 0 3	15·8
IUDR	14·9 ± 0·2	0	0

Thy.	10·4 ± 0·1	0·	0
GA + Thy.	8·8 ± 0·1	1·6 ± 0 1	19
IUDR	11·5 ± 0·1	0	2
GA + IUDR	8·0 ± 0 1	3 6 ± 0 1	37
Thy. + IUDR	10·3 ± 0 1	0	2
GA + IUDR + Thy.	8 1 ± 0 2	2 8 ± 0 1	26

tritium labelled IUDR into the DNA of chromosomes of *Vicia faba* root tip cells has been demonstrated[6]. These results suggest that incorporation of IUDR and other thymidine analogues into apical meristem cells of higher plants may result in both mutagenic and morphogenetic changes.

Arabidopsis thaliana (L.) Heynh., a facultative long-day plant, has been shown to respond to gibberellic acid (GA), under short day, by accelerated flowering[7].

The experiments reported here show that the thymidine analogue IUDR also promotes flowering in *Arabidopsis thaliana* after application to the vegetative meristem, and acts in an additive manner to enhance the effect of GA. Thymidine was found to have no stimulatory effect on flowering and did not significantly decrease the stimulation caused by IUDR and GA. FUDR at the same concentration completely suppressed growth and caused bleaching and death. However, both these effects were partially reversed by thymidine.

The plants used were derived from a single plant of a race 'Estland', and were cultured aseptically on mineral agar in test tubes. In the first experiment cultures were placed at 6° C for 30 h prior to transfer to a constant 25° C tube temperature, 800 ft.-candles light intensity, and 12-h photoperiod. In the second experiment the 6° C seed treatment was omitted without decreasing germination, though flowering dates of the controls differed. In both experiments drops of sterile 'Tween 20' (0·1 per cent in half-strength mineral solution) were applied to plant axils to facilitate penetration of the treatment solutions; the drops were shaken off before treatment chemicals were applied.

Experiment 1. Treatment solutions were sterilized in an autoclave. The syringe and 20-gauge needles used permitted application of 50 µl. of each solution to provide the following treatments: (*a*) control ('Tween 20'); (*b*) 5 × 10^{-4} M IUDR; (*c*) 2·10 × 10^{-4} M GA; (*d*) IUDR + GA applied consecutively. There was an average of 15 plants per treatment.

Experiment 2. Treatment solutions were sterilized only by 'Millipore' filtration. Treatments were applied aseptically using 1 c.c. syringes and 24-gauge needles, which enabled accurate placement of 20-µl. drops in the region of the growing apex. Treatments were applied consecutively to provide all possible combinations of the following main treatments: (*a*) control; (*b*) thymidine 5 × 10^{-4} M; (*c*) GA 2·10 × 10^{-4} M; (*d*) IUDR 5 × 10^{-4} M; (*e*) FUDR 5 × 10^{-4} M. There were ten plants per treatment combination.

The treatments were applied to 13-day-old plants, which were uniformly at the rosette stage with the third leaf pair not fully expanded. A plant was scored as flowering when the first flower opened. Six days after treatment with FUDR plants became bleached and showed complete growth inhibition. Eventually all FUDR-treated plants died. Delay of bleaching and different degrees of recovery were observed in treatments with thymidine plus FUDR. In these treatments 80 per cent of the plants were alive after 56 days, though renewed growth was either chlorotic or distorted. In 25 per cent of the plants flowering occurred and seed was set. In the absence of thymidine, FUDR caused 100 per cent eventual death in other treatment combinations.

Some distortion of new leaves produced after IUDR application occurred in several plants, but most were normal and the major effect was an acceleration of growth and production of pro-cauline leaves prior to stem elongation (Table 1). In both experiments IUDR and GA, either alone or in combination, induced earlier commencement of reproductive development and earlier flowering (Figs. 1 and 2). These effects were highly significant and did not interact. Thymidine did not reverse the IUDR effect on flowering time. The effect of IUDR on flowering time was less than that of GA and could be distinguished from GA additionally by a highly significant reduction in the mean stem-height at flowering. This effect on stem-height was significantly reversed by thymidine but not significantly by GA (Table 2) The observed effects are magnified by growth from primary events occurring in the apical meristem. The absence of interaction between GA and IUDR or thymidine indicates that the hormone and nucleoside sites of action are different and non-competitive.

Table 2 EFFECT OF GIBBERELLIC ACID (GA), THYMIDINE (Thy.) AND 5-IODODEOXYURIDINE (IUDR) ON FLOWERING TIME AND PLANT HEIGHT AT FLOWERING IN *Arabidopsis thaliana* (L.) HEYNH

Treatment	No. of plants	Days to flower	Height at flowering

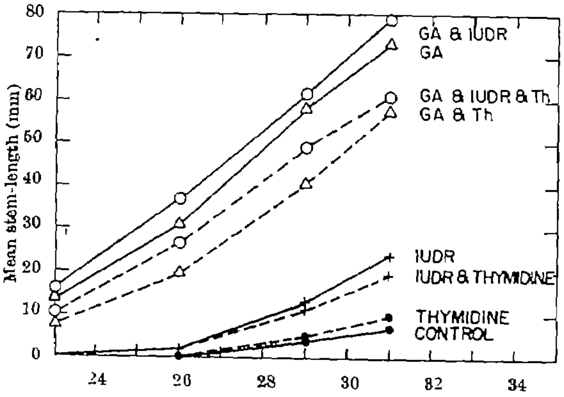

Fig. 1. Effect of GA, IUDR and thymidine on stem-elongation

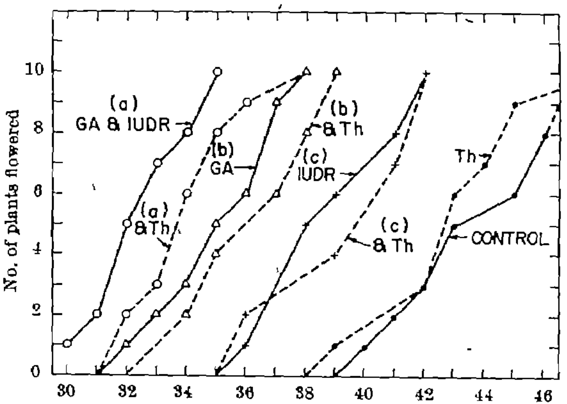

Fig. 2. Effect of GA, IUDR and thymidine on flowering-time in *Arabidopsis thaliana* (L.) Heynh.

Thymidine reversal of FUDR inhibition occurs at the free nucleotide-level, since FUDR acts primarily by blocking the formation of thymidylic acid from uridylic acid by inhibiting the methylating enzyme thymidylate synthetase[3,8]. IUDR, however, has not been shown to bind this enzyme but does replace thymidine in the synthesis of DNA and is effectively incorporated even in the presence of normal cellular levels of thymidine into bacterial, mammalian and plant root meristem DNA. Since there is little turnover of formed DNA, then if the site of action on morphogenesis of IUDR is at the DNA polymer-level, rather than at the free nucleotide-level, interaction with thymidine would tend to be weak; for once IUDR DNA is formed, free thymidine can no longer be an effective competitor. At the free nucleotide-level, however, strong interaction should result from the presence of added equi-molar amounts of IUDR and thymidine. The fact that a weak interaction was observed, and was significant for the specific IUDR effect on height at flowering, indicates that the IUDR effect is due to the analogue molecule, and is consonant with a DNA site of action.

An interpretation of these preliminary results might be based on the concept that a precocious induction of floral morphogenesis occurs following temporary impairment of the active nuclei of the vegetative meristem. This could result in the release of normally relatively quiescent nuclei to form the reproductive meristem. Other nucleoside analogues, particularly BUDR, may act similarly to IUDR.

Note added in proof. In subsequent experiments now reported[9], BUDR has caused the same morphogenetic effect as IUDR.

I thank Hoffman LaRoche Inc. for their gift of FUDR. This work was carried out under the auspices of the U.S. Atomic Energy Commission.

SYNTHETIC DIET FOR SILKWORM RAISING

By T. FUKUDA, M. SUTO, T. KAMEYAMA and S. KAWASUGI

Sericultural Experiment Station, Suginami-Ku, Tokyo

PREVIOUSLY, some of us[1,2] have succeeded in rearing the whole larval stage of not only the domestic silkworm (*Bombyx mori*) but also wild silkworms (*Philosamia cynthia ricini*[3], *Antheraea pernyi*[4], etc.) on an artificial food which consists mainly of the dry leaf powder of plants such as mulberry, castor-oil plant or oak. We have since tried replacing the leaf powder with some simple nutrients to make a synthetic diet for each silkworm. This article is concerned with the preparation of a synthetic diet which makes possible the rearing of the silkworm, *Bombyx mori*.

We found that the silkworm ate continuously a diet composed of 1 g sucrose, 6·5 g cellulose powder, 50 mg β-sitosterol and 11 ml. of water, solidified with 1·5 g potato starch. In preparing the synthetic diet, some nutrients necessary for growth of the larvæ were added in place of some parts of cellulose powder, which occupies a great portion of the basal diet. These were a mixture of amino-acids, vitamins or mineral substances (Tables 1–3), on the basis of the amount in the mulberry leaves, determined by the microbiological method, and the others. The alcohol extracts of mulberry leaves added, when necessary, to the diet to stimulate feeding was prepared by extracting dry mulberry leaves with hot absolute methyl alcohol for 5 h and by removing the alcohol by reducing pressure. A mixture of all the vitamins, except for ergosterol and β-carotene, was stored in a refrigerator in solution. A certain amount of ergosterol, β-sitosterol, alcohol extracts of mulberry leaves and β-carotene were respectively dissolved in ether, and were present in a certain amount of the cellulose powder added. The ether was completely removed first.

The synthetic diet was prepared as follows. A beaker containing the sucrose, the amino-acid mixture, the vitamin mixture, except for the ergosterol and the β-carotene, and water was heated, and the hot solution was poured into a beaker containing the potato starch, the cellulose powder, each cellulose powder containing the β-sitosterol, the ergosterol, the β-carotene and the alcohol extract of mulberry leaves (when necessary) and mineral substance mixture. The contents were well stirred, formed as a pie, steamed for 3 min and stored in a refrigerator. The newly moulted fifth instar larvæ, hybrids between Nichi 122 × Nichi 124 and Shi 115 × Shi 124, were reared, according to the procedure described in a previous paper[1], on a synthetic diet in a box at a temperature of 25° C and at 73 per cent relative humidity until they began spinning their cocoons. The diet was cut in slices 0·1–1 mm thick. These were fed to the silkworms during the fifth stage twice daily at 12-h intervals. The composition of synthetic diets prepared is shown in Table 4, and the growth of the silkworm reared on the diet in Table 5. Five silkworms were tested for each experiment.

The silkworms scarcely ate diet 20 on the first day, but did so continuously after the second day. The body-weight of the silkworms reared on the diet increased gradually after two days, and was about doubled by the eighth day. Among five silkworms tested, two became mature larvæ at the eleventh day, and afterwards spun their silk thread, but the amount was only 21 mg per larva. Three silkworms died after maturation; a larva at the tenth day and the two at the eleventh day. In the larva which died at maturity the pair of silk-glands were well developed and were equal in size to the silk-glands of the silkworm at the fifth day of the fifth stage reared on fresh mulberry leaves. The silkworms scarcely ate diet 15, which differs from diet 20 in content of sucrose and β-sitosterol. The silkworms reared on diet 10, containing alcohol extract of mulberry leaves the concentration of which corresponds to 2 per cent for the diet, and 4·4 per cent for its dry matter, did not eat so much for the first day, but fed comparatively well after becoming familiar with the diet. The body-weight of the silkworms reared on diet 10 increased four times in body-weight. All the five silkworms tested became matured larvæ, and spun their cocoons. The weight of the cocoon fibres was 83 mg (av.), and the value was about 70 per cent of the weight of the cocoon fibres produced by the silk worms reared on a diet[2] which consisted mainly of the dry mulberry leaf powder.

Generally speaking, it is necessary, in rearing silkworm larvæ on artificial food, to take care in the choice of their races, because the acceptance by silkworm larvæ of the diet varies remarkably with race. A diet, such as 10, containing small amounts of the alcohol extracts of mulberry leaves, gives a satisfactory result in comparison with a diet such as 20, which contains no alcohol extract. This fact seems to suggest to us that there are some important substances which stimulate the feeding of silkworms in the alcohol extracts of mulberry leaves in addition to β-sitosterol[5,6] and sucrose. It will be clear, judging from an experimental result, that silkworms reared on a diet from which some amino-acids or some vitamins had been removed (diet 10) died within three or four days. In this article it is shown that it is possible to rear silkworms on synthetic diets. At present an investigation to improve the composition of the synthetic diet prepared is being carried out. Recently we also succeeded in preparing a synthetic diet which consists of agar-agar, sucrose, amino-acids, mineral substances, vitamins, cellulose powder, β-sitosterol and water for the silkworm raising.

LETTERS TO THE EDITOR

GEOPHYSICS

Nuclear Explosions and Normal Mode Oscillations of the Earth

The article in *Nature*[1] under the title "Recent Nuclear Explosions and Earth Tides" suggesting that nuclear explosions can excite the normal mode oscillations of the Earth needs careful reconsideration.

The free oscillations of the Earth, though theoretically predicted even in the nineteenth century, have been experimentally observed only on two occasions. The first observation was by Benioff *et al.*[2] when they reported fifty-seven minute waves on strain seismograph records after the Kamchatka earthquake of November 4, 1952. The great Chilean earthquake of May 22, 1960, also caused very noticeable oscillations and several of the spheroidal and toroidal modes of the Earth were detected and identified from gravity meter and strain seismograph data. Ness, Harrison and Slichter[3] used a very high resolution La Coste–Romberg gravity meter with the smallest measurable signal of the order of 0·023 microgal (r.m.s. noise figure) to record the Chilean earthquake and detected several of the spheroidal modes (only these are observable on gravity meters) in the period range of 3–55 min. Many other observational and theoretical discussions on the subject have appeared and a comprehensive bibliography is given at the end of the masterly discussion on toroidal oscillations of the Earth by MacDonald and Ness[4].

The energy demand to excite normal mode oscillations of the Earth is enormous and hence only very large earthquakes cause noticeable effects and even then very sensitive instruments are required to detect them. The Kamchatka earthquake had a magnitude of 8·25 and the Chilean earthquake was even bigger with a magnitude of 8·75. These magnitudes correspond to an energy release of the order of 10^{27} ergs. The largest nuclear bomb exploded so far communicated energy of the order of 10^{20} ergs (magnitude of equivalent earthquake, 5·5–5·75) to the ground. It will indeed be an 'earth-shaking' effect if this small amount of energy (relatively speaking) can excite free oscillations of the Earth.

One should not lose sight of the fact that gravity meters and vertical seismographs are very sensitive to barometric fluctuations, and whether the Askania gravity meter referred to in the note in *Nature*[1] could be the exception is a point worth investigating.

WHILE reporting the effects of nuclear explosions on the gravimeter installed in our laboratory, it was mentioned that possibly sometimes the free oscillations of the Earth could also be observed. It is obviously necessary that an adequate amount of energy will have to be communicated to the Earth for this to occur and in order to identify these oscillations the records have to be harmonically analysed. This is now being done.

The instrument is pressure-tight and shows a change of less than 0·05 mgal. for pressure variations corresponding to a difference in height of 500 metres. The observed changes in g are much greater than this and hence may not be attributed to the pressure fluctuations.

Annual Change in the Declination ('Variation') in Western Scandinavia and the North Sea

THE annual change (secular variation) for about 10 years (1941–52) in the declination was remarkably constant, namely + 8′ (E.), for Norway, Denmark, Sweden and also for the North Sea (Lerwick, Shetland). However, starting in 1952, there has been a gradual decrease in the annual change, and for the period 1952–60 it was about + 5′ (dropping from 8′ to 4′). Fig. 1 gives the secular change for three magnetic observatories, Lerwick (Shetland), Rude Skov (Denmark) and Tromsø (Norway). For Rude Skov it may be seen that there is a gradual decrease, disregarding scatter, from 11′ to 4′ during the period 1927–60, apart from the temporary stagnation mentioned here. The same tendency may be shown for

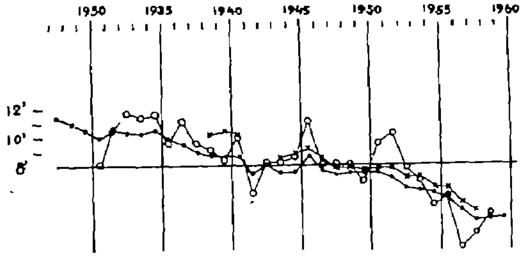

Fig. 1. Annual secular variation in declination for the observatories in Lerwick (Shetland) (×), Rude Skov (Denmark) (●) and Tromsø (Norway) (○)

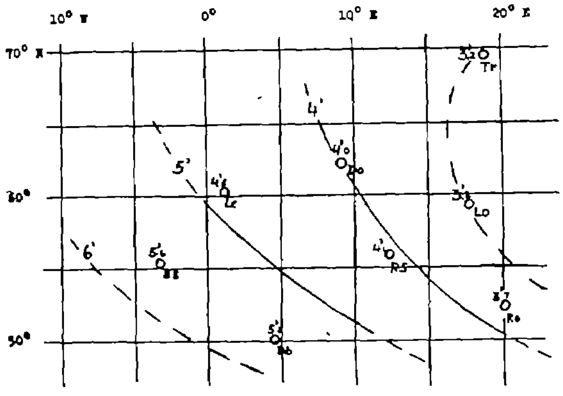

Fig. 2. Secular change in declination 1957/58 for eight north European observatories

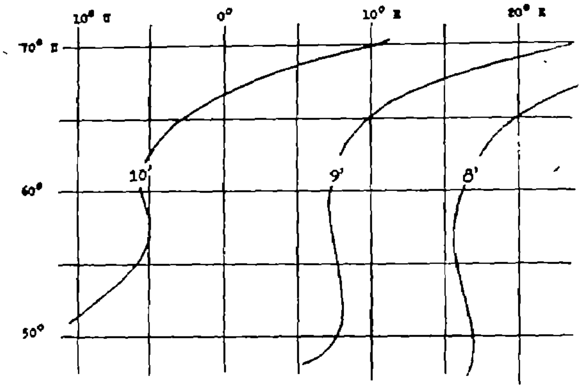

Fig. 3. Secular variation in declination epoke 1942.5 for north Europe (after ref. 1). The curves represent smoothed values

other north European observatories. The rough sketch in Fig. 2 shows the secular variation in declination for 1957/58 for eight north European observatories. Comparing Fig. 2 with Fig. 3, which gives the isopors (lines of equal annual secular variation) for epoke 1942.5[1], it can be seen that the pattern of isopors is still moving westward.

We are directing attention to the change in the secular variation in the declination because we have found that many sea maps west and south of Norway from various publishers have not brought the secular variation up to date, but operate still with the old value of + 8′.

PHYSICS

A Characteristic of Electron Emission Curves

DURING an investigation of the breakdown mechanism in vacuum, the pre-breakdown currents arising from copper and steel electrodes under alternating voltages were measured. The general form of the apparatus has already been described[1]. The total current, capacitive plus emission current, was measured by noting the voltage across a resistor of known value in the earth connexion of the low-voltage electrode. Once emission started, certain peaks of the voltage across the resistor increased in magnitude. The value of the emission current was found by subtracting the estimated capacitive current from the total current obtained from these peaks.

The electrodes were polished with fine emery cloth and washed with ether. Thus the surface of the electrodes was rather rough and heavily oxidized. Measurements were made over a gap-range of 0·5 mm to 2 mm and a 'stress'-range of 2×10^{5} to $4{\cdot}3 \times 10^{5}$ V/cm, where stress is taken simply as applied voltage divided by electrode separation.

The exact mechanism of electron emission from such surfaces at room temperatures and at these stresses is not clearly understood. Some investigators support either a Schottky type emission or a Fowler–Nordheim type emission, or modifications of these[2–5].

Table 1. ESTIMATED CONSTANTS FROM FOWLER–NORDHEIM PLOT FOR 1-MM COPPER ELECTRODE GAP

Stress range (V/cm)	Estimated work function (eV)	Estimated emission area (cm²)
2×10^{5}–3×10^{5}	0·12	$2{\cdot}9 \times 10^{-8}$
3×10^{5}–5×10^{5}	0·03	$8{\cdot}3 \times 10^{-11}$

When the present results were plotted in either Schottky or Fowler–Nordheim form straight-line relationships were obtained, but in each case, as shown in Figs. 1 and 2, a sharp bend occurred in the curves. The bends arose in a roughly constant stress region between $2{\cdot}3 \times 10^{5}$ V/cm and 3×10^{5} V/cm independent of material. The magnitude of the currents was, however, strongly dependent on material. Table 1 shows the estimated work functions and emitting areas, for copper electrodes and a 1-mm gap, based on a Fowler–Nordheim plot, assuming no intensification of the field at the surface.

Nicholas[6] and Watts[7] have investigated a similar effect in the characteristics of emission from electrodes in gases. Critical stresses reported by Nicholas were $2{\cdot}5 \times 10^{5}$ V/cm for a nickel cathode and $2{\cdot}2 \times 10^{6}$

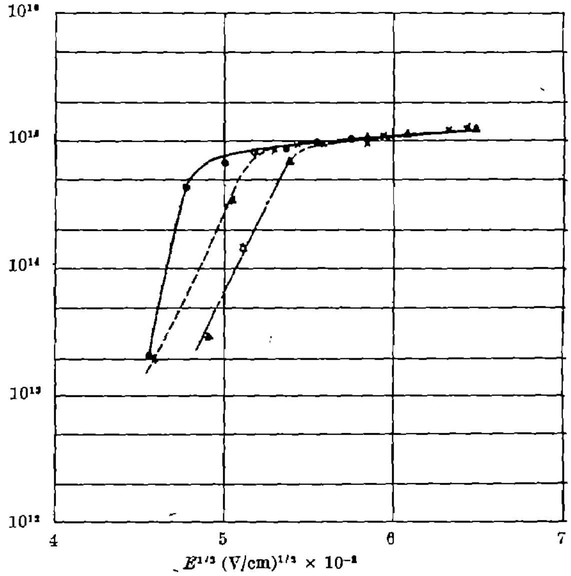

Fig. 1. Emission currents from copper electrodes Schottky plot ——, 2-mm gap, – – –, 1-mm gap, —·—, 0·5-mm gap

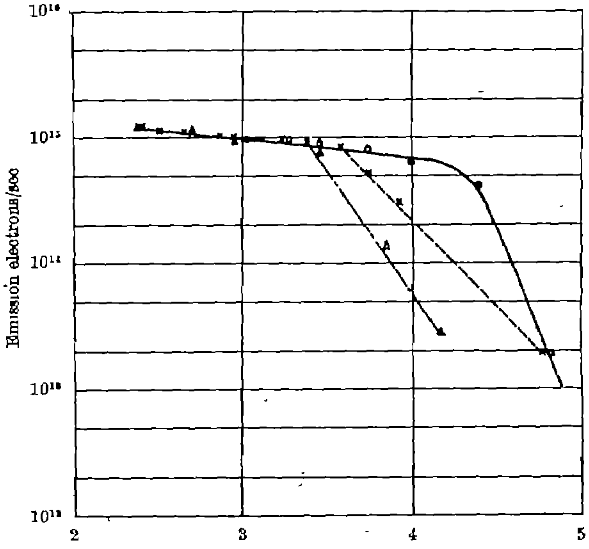

Fig. 2 Emission currents from copper electrodes. Fowler–Nordheim plot. ○, 2-mm gap; ×, 1-mm. gap; △, 0·5-mm gap

V/cm for a gold cathode; temperature dependence of the emission has also been investigated[8].

Measurement of Relaxation Times of Macromolecules by the Kerr Effect

Information on macromolecules may conveniently be found by application of the Kerr electro-optic effect. When an electric field in the form of a pulse of rectangular shape is applied to a solution the molecules will attempt to line up to a state of minimum potential energy during the rise period of the pulse. Once lined up they will remain stationary in alignment when the field amplitude is constant and then become disorientated by Brownian motion when the field ceases. If the orientation is sufficient the solution will exhibit birefringence, but since large molecules will take time to come into alignment and to return to a state of random array the rise and decay of the birefringence will lag behind that of the applied field. In general, therefore, a gradual increase of birefringence occurs, which may or may not reach a steady value according to the duration of the pulse, followed by a decay. Observations of the rise can give information on dipole moments and the steady value can be related to the Kerr constant and to molecular anisotropy. The decay for a solution of k types of molecules occurs according to the equation[1]:

$$\Delta n = \sum_{1}^{k} \delta n_i e^{-t/\tau_i}$$

in which Δn is the birefringence at any time t, δn_i is the maximum birefringence shown by molecules of type i and τ_i is a relaxation time which is a measure of the time the molecule takes to depart from its position of minimum potential energy. If it be assumed that the effect of the field is to produce rotation of the entire molecule then the polar or non-polar nature of the molecule is made manifest by the symmetry or asymmetry of the birefringence rise and fall, and τ_i can be related[1] to the rotary diffusion constant D_i by the equation $\tau_i = 1/6D_i$. Values of relaxation times and diffusion constants obtained in this laboratory are reported here.

The experimental arrangement used is as follows: a collimated beam of light is linearly polarized by a polarizing prism P, traverses the cell C containing the solution, a quarter wave plate Q and then passes through an analyser A on to a photon-multiplier PM. P and A are crossed, and the direction of the field is at 45° to the vibration direction of P and A. The azimuth of Q is zero with respect to the vibration direction of P. The cell is of metal lined with 'Teflon' and contains two parallel stainless steel electrodes centrally placed at a distance 0·25 cm apart. The length of path between the electrodes is 2 cm. Rectangular pulses of duration 1·7 μsec with a rise and decay-time of 2×10^{-8} and 3×10^{-8} sec respectively, and having amplitudes variable up to 8 kV, are applied to the electrodes. The pulses are generated by a hydrogen thyratron and delay line assembly. When the liquid becomes birefringent light passes through A on to PM and the photon-multiplier output is displayed on a cathode ray oscillograph able to show fast rise times. To increase the sensitivity the linear detection method described by Badoz[2] has been used. For this purpose a second Kerr cell filled with nitro-benzene to which a constant potential is applied is inserted between P and C. The apparatus is suitable for investigation of molecules having relaxation times of the order of 5×10^{-8} sec and greater.

The shape of the applied electrical pulse is shown in Fig. 1*a*; it is inverted simply because it was easier to obtain a good photographic trace this way. Representative traces obtained with birefringent liquids are given in Figs. 1*b*, 1*c* and 1*d*. Traces obtained with glycine, which has a relaxation time of about 10^{-11} sec (ref. 3), were almost identical with that of Fig. 1*a*, which showed that the decay inherent in the apparatus was negligible compared with that shown by the solutions examined. Measurements taken off the traces using a double traverse microscope enabled graphs of log Δn against t to be plotted. When excessive noise

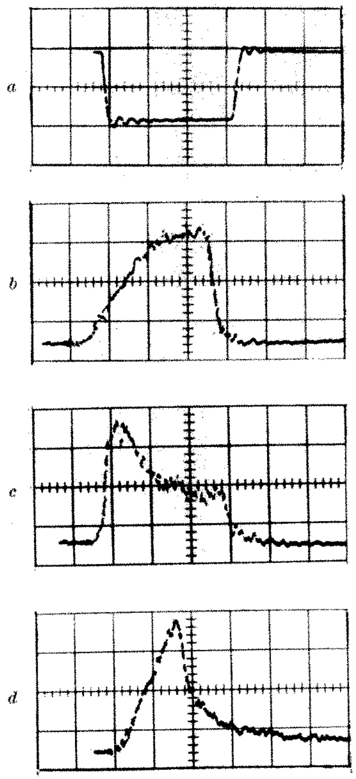

Fig. 1. (*a*) Applied electrical pulse 6 kV (shown inverted). Photomultiplier output pulses for (*b*) bovine γ-globulin, (*c*) β-lactoglobulin, (*d*) carboxymethylcellulose. Each division of time-scale represents 0·5 μsec in (*a*), (*b*) and (*c*) and 1·0 μsec in (*d*)

was present smooth curves were drawn through the traces to average out the noise before taking measurements. From the graphs relaxation times were found. The method quickly enables reliable results to be obtained and these are given in Table 1 for a number of substances. For most solutions two relaxation times were found which may be due to the presence of two components. Velocity sedimentation runs using a Spinco model *E* analytical ultra-centrifuge were made to check this. An example is shown in Fig. 2 for β-lactoglobulin in which the presence of two components is indicated.

Table 1. RELAXATION TIMES τ AND ROTARY DIFFUSION CONSTANTS D

	Solute	Concentration (per cent wt.) and temperature (° C.)	τ (10^{-8} sec)	D (10^{3} sec^{-1})
1	Carboxymethyl-cellulose	0·02 (23°)	146; 24	114; 694
2	β-Lactoglobulin (cows' milk)	1·0 (22°)	35; 7·6	476; 2,193
3	Ribonucleic acid (sodium salt, yeast)	1·00 (25°)	< 10	> 1,667
4	Ribonucleic acid (sodium salt, yeast)	1·00 (25°)	45; 16·5	370; 1,010
5	Bovine plasma albumin	1·0 (23°)	12·2	1,366
6	Bovine-γ-globulin (fraction II)	1·0 (23°)	21·5	775
7	Sodium alginate	0·02 (20°)	86; 32	194; 521
8	Polymethacrylic acid (sodium salt)	0·02 (23°)	66; 22	253; 758
9	Sodium polyphosphate	— (20°)	40; 100; 284	417; 167; 58·7
10	Deoxyribonucleic acid (calf thymus)	0·01 (25°)	3,460; 20,000	4·82; 0·833

Water was the solvent in all cases except No. 4, which was in 50 per cent water/glycerol. Concentrations of 2 and 6 were taken before centrifuging at 3,000*g* for 15 min. Nos. 1–4 were supplied by Light and Co., Nos. 5 and 6 by Armour Pharmaceutical Co. No. 7 was a commercial sample of 'Manucol' obtained from Alginate Industries. Nos. 8–10 were supplied by Dr. K. A. Stacey, Experimental Radiopathology Research Unit, Hammersmith Hospital. Nos. 5 and 6 appeared slightly disperse.

The method has also been used to investigate the influence of *p*H, of variations in ionic strength, concentration and temperature and the effects of different solvents with the view of obtaining information on mechanisms responsible for dielectric polarization in macromolecular solutions[4]. Studies of the effect of ribonuclease enzyme on ribonucleic acid (RNA) have also been performed and preliminary results indicate that the action of the enzyme in breaking down the RNA can be accurately and quickly followed by this method. It is hoped that detailed results will be published later.

One of us (P. I.) thanks the Department of Scientific and Industrial Research for the award of a postgraduate research studentship. The centrifuge used was purchased by a D.S.I.R. grant for special researches.

CRYSTALLOGRAPHY

Sucrose Crystallization

FURTHER investigations of the crystallization of sucrose have continued to reveal items of general crystallographic interest[1].

The effect on crystal form of an increasing degree of supersaturation was dealt with in the last report of this series. Spherulitic and radialitic nucleation and growth were recorded as characteristic of supersaturations of 3·0 and greater. Both nucleation incidence and growth-rate appear to peak at about 2·5 supersaturations, thereafter falling off, until at really high supersaturation the near amorphous system may take years to crystallize. Evidence now justifies recording that at intermediately high supersaturation a new type of nucleation and growth-form is developed. Instead of the normally large number of component ray crystals produced at supersaturations 3·0 and 4·0, at this much higher concentration the crystal system produced appears to be relatively simple, being composed of several rays, or, even of one crystal only, as revealed by rotation under the polarized light microscope. Growth is very slow and the contours of the crystals are generally somewhat curved[2] as compared with normal rectilineal contours of monocrystals grown in the region of 1·1 supersaturations. Dendritic growth may also develop if given sufficient time, and this again appears different in style when compared with that produced at the lower range of supersaturation.

I have found that hopper crystals frequently provide an excellent natural record of habit modification during growth. A ¼-in. layer of pure sucrose

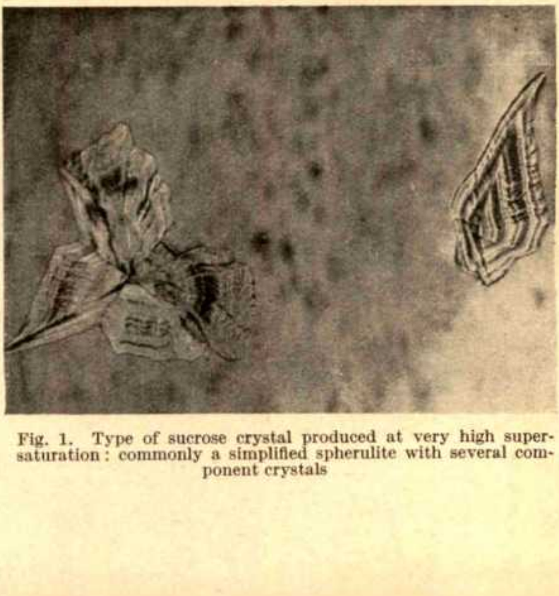

Fig. 1. Type of sucrose crystal produced at very high supersaturation: commonly a simplified spherulite with several component crystals

solution in a covered Petri dish, stored for months in a normal air-conditioned room, will slowly crystallize to dryness, some hopper crystals frequently being present. Examples of the development of needle to rectilineal, also of triangular to hexagonal contours have been so recorded, and one micrograph records the initial development followed by the elimination of a subsidiary face during the growth of such a hopper crystal.

The sucrose crystal exhibits many different forms of layer growth[3]. We now know that inclusions abound in sucrose crystals, of dimension from molecular to macroscopic. As a result, there is so intense a distribution of faults in the development of the lattice as to generate some form of layer growth continuously. It seemed to me probable that long-continued uniform growth might be expected to favour the perpetuation of growth spirals. This regular growth may easily be achieved by means of a humidator with vapour pressure control, as described in my previous report. Such a system was therefore set up, using as seed several small clean cleaved sections from large Kandi crystals. This was permitted to develop without disturbance for four months in a constant temperature room. At the end of this period the humidator was opened up and the crystals, which had grown to an average size of one inch in length, were seen to have developed in most cases, one large spiral covering the whole 100 face. Under suitable lighting conditions, this spiral could easily be seen with the unaided human eye.

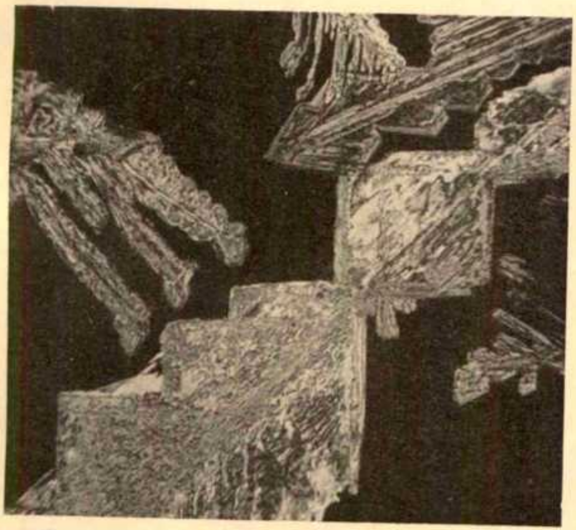

Fig. 2. Dendritic growth under same conditions as Fig. 1

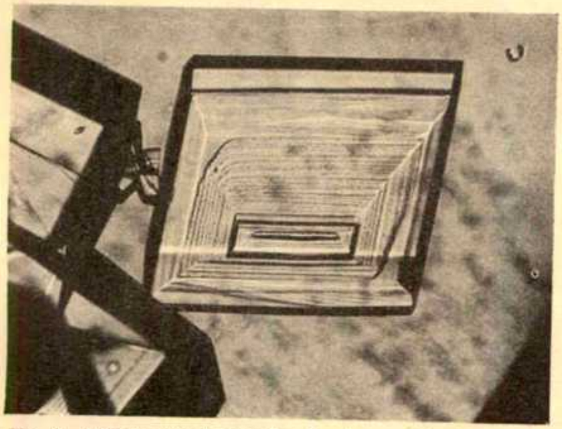

Fig. 3. Hopper crystal recording development from needle to rectilineal contour

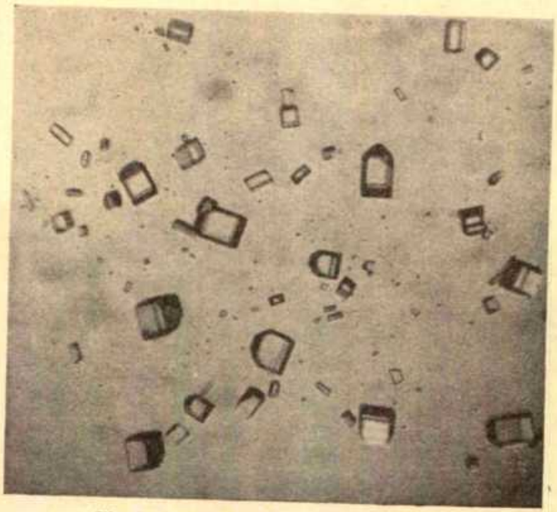

Fig. 4. Result of differential rate of growth

In previous published reports[4] I have given evidence of the differential growth-rate of sucrose crystals growing freely in the same system. This would be a logical and predictable result consequent on: (*a*) the increasing solubility of micro-crystals with decreasing size, also of (*b*) the varied efficiency of the various growth mechanisms. Cumulative evidence appears to indicate that the former is significant up to a crystal length of 10μ or thereabouts. This may be demonstrated prettily by introducing fondant seed crystals of up to two or three microns length in solutions of very low supersaturation, when some, mainly the larger crystals, will grow with increasing speed, while others remain static in size. In an accurately temperature-controlled system one should be able to assess the solubility at various sizes within the range of size visible under the microscope. This has been recorded much more informatively by means of time-lapse cine-micrography, but the final stage of one such growth run is shown in Fig. 4.

CHEMISTRY

Fluorescence of Some Substituted Benzenes

Some mono- and di-substituted benzenes fluoresce in aqueous solution. Phenol, for example, fluoresces in the ultra-violet and the salicylate ion in the visible region of the spectrum. Williams[1] pointed out that the fluorescent mono-substituted benzenes were those containing the classical *ortho-para*-directing groups. We have now examined this phenomenon more closely and also determined the quantum efficiency of fluorescence using a commercial Aminco-Bowman spectrophotofluorimeter.

The compounds examined were dissolved in water using a little ethanol to assist solution where necessary, and measurements of fluorescence were made at a concentration of 1 μg/ml. Corrected data were obtained as follows. The activation and fluorescence wave-length scales were corrected with a 'Pen Ray' mercury lamp as recommended by the manufacturers of the instrument[2]. The activation system of the fluorimeter, which consists of a high-pressure Osram 150-W xenon lamp, diffraction grating, and mirrors was calibrated from 230–420 mμ by Parker's potassium ferric oxalate actinometer method[3]. The fluorescence system, consisting of diffraction grating, mirrors, and an RCA *IP* 28 photomultiplier tube, was calibrated between 250 and 420 mμ by reflecting light from the calibrated activation system into the fluorescence system by means of a Hilger–Watt front-silvered, optically flat mirror (1 cm²) placed at 45° in the cell compartment and measuring the photomultiplier response to this light every 10 mμ on the fluorescence monochromator. Between 380 and 600 mμ the fluorescence system was calibrated using a modification of White's method[4] which involves using a lamp of known colour temperature. Quantum efficiencies (Q.E.) were calculated using the comparative method of Parker and Rees[5]. The calibration was checked against compounds of known quantum efficiency using quinine bisulphate in 0·1 N sulphuric acid (1 μg/ml.) as standard (Q.E. 55 per cent[6]). The following efficiencies were found: eosin in 0·1 N sodium hydroxide, 18·3 per cent (cf. Parker and Rees[5], who give 23 per cent), fluorescein in 0·1 N sodium hydroxide, 85 per cent (72 per cent[5]), rhodamine *B* in ethanol, 66·8 per cent (69 per cent[5]), and anthracene in ethanol, 36 per cent (28 per cent[5]).

The results for some mono-substituted benzenes are shown in Table 1, and it is clear that under our conditions only one type of mono-substituted benzene fluoresces. In this type of compound the substituent group contains an unshared pair of electrons on the atom adjacent to the ring and the electronic mechanism is $\overset{\curvearrowright}{Ph\longrightarrow R}$, the inductive effect being negative ($-I$) and the mesomeric effect being positive ($+M$). However, not all compounds of this type showed fluorescence, for chlorobenzene, bromobenzene and acetanilide appeared to be non-fluorescent. This suggests that the occurrence of fluorescence depends on mesomerism and the consequent conjugation of the group with the benzene ring. In the fluorescent compounds, for example, phenol, aniline and fluorobenzene, the mesomeric effect is known to be more dominant than in a compound such as chlorobenzene (for example, ref. 7). The dominance of the mesomeric effect is reflected in the value of the extinction coefficient (ε_{max}) of the benzenoid absorption band of these compounds[8] (Table 1).

Table 1 also shows that mono-substituted benzenes of other electronic configurations are non-fluorescent. Those containing *meta*-directing groups and where *M* is negative are non-fluorescent, as are also those where the electronic configuration is influenced by the inductive effect only. The phenoxide ion has the configuration $+I$ $+M$, but is non-fluorescent. It is possible that in this case the π-electrons, which are responsible for fluorescence, are too strongly localized to allow fluorescence.

Table 1 also shows that the quantum efficiency of the fluorescent compounds is low and is less than 10 per cent. The most efficient compound is *N,N*-dimethylaniline (Q.E. 9·7 per cent) and the least is fluorobenzene (Q.E. 0·7 per cent). The quantum efficiencies quoted can be roughly correlated with the known strength of the mesomeric effect.

Table 1. FLUORESCENCE OF MONO-SUBSTITUTED BENZENES, C_6H_5R
Concentration used was 1 μg/ml. in water
Nitrogen was bubbled through the solution for 15 min before fluorescence was measured

R	Benzenoid absorption $\lambda_{max.}$ (mμ)	$\varepsilon_{max.}$	Excitation max (mμ) obs. (Electronic configuration, $-I + M$)	Excitation max (mμ) corr.	Fluorescence max (mμ) obs.	Fluorescence max (mμ) corr.	Quantum efficiency (%)

$NHCOCH_3$	no benzenoid band						

R	Non-fluorescent compounds: Electronic configuration	*R*	Electronic configuration
COOH NO_2 SO_2NH_2 CHO AsO_3H_2	$-I$ $-M$	$\overset{+}{N}H_3$ $\overset{+}{N}(CH_3)_3$	$-I$
		CH_3	$+I$
COO^-	$+I$ $-M$	O^-	$+I$ $+M$

In Table 2 a list is given of the fluorescence of some *p*-substituted anilines and phenols. Referring to quantum efficiencies, the *p*-F group considerably enhances the fluorescence of aniline, but has little effect on that of phenol. The *p*-chloro group diminishes the fluorescence of both aniline and phenol, whereas *p*-bromoaniline and *p*-bromophenol are non-fluorescent. The weak *m*-directing groups, SO_2NH_2 and SO_3^-, increase the fluorescence of aniline, while the strongly *m*-directing NO_2 group abolishes the fluorescence. *p*-Methyl and *p*-methoxy groups both increase the fluorescence of aniline and phenol. *p*-Aminoacetanilide shows a very weak fluorescence. It is probable that the fluorescence of di-substituted benzenes depends on the resultant effect of both groups (which may oppose or enhance each other)

* Sulphanilamide undergoes rapid photo-decomposition.

† The fluorescence of *p*-anisidine and *p*-toluidine were markedly affected by temperature. At 8° C., the fluorescence intensity of these two compounds is about twice that at 28°.

on the extent of delocalization of π-electrons of the benzene ring. The overall qualitative picture suggests that the more delocalization there is, the more fluorescent the compound is likely to be. On these grounds we have been able to predict whether a *p*-substituted benzene would fluoresce. Thus one could predict that a *p*-substituted aniline or phenol containing a weak *m*-directing group such as SO_3^-, SO_2NH_2, and AsO_3H_2 and its ionized forms would fluoresce; in fact, the fluorescence of *p*-arsanilic acid increases with each step in the ionization of the AsO_3H_2 group. Bromo- and nitro-groups abolish, whereas chloro- and acetamido-groups diminish, the fluorescence of aniline and phenol. Fluoro, methyl and methoxy groups usually enhance or do not alter, rather than diminish, the fluorescence. Other compounds have been studied, but the results will be reported elsewhere.

Paper Chromatography of 2-Halogenated Carboxylic Acids : *N*,*N*-Dimethyl-*p*-phenylazoaniline as an Acid-Base Indicator Reagent

IN work directed toward the separation of several volatile 2-halogenated carboxylic acids by paper chromatography, it was found desirable to develop these acids, not, as is usually the case, in the form of their salts[1], but as the free acids. The so-called 'swamp acid' technique[2] used for this purpose simply involves the use of a relatively large quantity of some acid as part of the solvent system, usually acetic or formic. This acid is necessary to repress ionization of the unknown acid, which would otherwise give rise to 'tails' or 'ghosts'. However, it soon became clear in working with the 2-halogenated acids that removal of the 'swamp acid' preparatory to spraying with the more common acid-base indicators also removed the volatile unknown acids. Therefore, some scheme had to be found for locating the unknowns in the presence of the 'swamp acid'.

It was found that water solutions of these 2-halogenated acids had a lower *p*H than a solution of acetic (or formic) acid in water. In addition, it was found that the dye, *N*, *N*-dimethyl-*p*-phenylazoaniline, changes from yellow to red at a *p*H of 2·9. This change is just right so as to indicate these acids and not acetic or formic. Therefore, if this indicator is used it is unnecessary to remove the 'swamp acid' since its presence does not interfere with the detection of the unknown acids.

It has been established that the following acids can be detected with this indicator in the presence of acetic acid: chloroacetic, trichloroacetic, 2-chloropropionic, 2,2-dichloropropionic, 2,2,3-trichloropropionic, 2-chlorobutyric, 2,2-dichlorobutyric, 2,3-dichlorobutyric, and 2-bromoacetic acids. The lower limit of detection in the case of 2-bromoacetic acid was 3 μg.

The procedure for detection of unknown acids using this spray reagent is as follows: After development of the chromatogram, the acids were located by spraying (without drying) with a 0·1 per cent solution of *N*,*N*-dimethyl-*p*-phenylazoaniline in 90–95 per cent isopropyl alcohol. The location of the spots is shown by a red-purple colour, stable for long periods of time, on a bright yellow background. If the spot does not appear immediately on spraying, the paper can be carefully dried in a stream of cold air until the spot shows up.

This technique, that is, spraying the indicator solution on top of the 'swamp acid' to give a satisfactory definition of the volatile acid in question, should be of quite general application whenever there is a measurable *p*H difference between the 'swamp acid' and the unknown acid, and the proper indicator can be found to take advantage of this difference.

An Application of Paper Electrophoresis to the Examination of Completeness of Reaction and Purification in the Synthesis of Radioactive Compounds

THE usefulness of [(carboxymethylimino)*bis*(ethylenenitrilo)]tetraacetic acid (DTPA) in correcting iron chlorosis induced by lime in plants has been well documented[1,2]. DTPA labelled with carbon-14 was required to facilitate studies concerning the metabolism of the compound in plants; accordingly, the synthesis was undertaken. The method used involved an alkylation of diethylenetriamine (DET) with bromoacetic acid. In preliminary work, it became evident that the usual methods available for determining chelating materials, such as titration with calcium ion in the presence of oxalate or sprays with a nickel-dimethylglyoxime reagent, would not be satisfactory for following the course of the reaction. These reagents will neither indicate the distribution nor detect all the compounds arising as a result of incomplete alkylation. Paper electrophoresis was found to be a very powerful tool for the delineation of all the compounds formed in the reaction.

Bromoacetic-2-^{14}C acid (0·296 mmole, specific activity 1·69 mc./mmole) in benzene (1·6 ml.) in a 3-ml. test tube at 5° was treated with 96 μl. of 6·28 N sodium hydroxide (0·60 mmole). The addition was made in three portions with stirring. DET (6·18 mg, 0·06 mmole) in water (35 μl.) was then added with stirring to this cold solution. The reaction mixture was allowed to stand at room temperature for 4·5 h with occasional stirring. At the end of this time, one drop of an ethanolic solution of 'Eriochrome Black *T*' indicator (*Color Index* No. 203) was added and the reaction mixture was made slightly acid with 0·80 N hydrochloric acid (0·20 ml.). This indicator and its use in 'Versene'(R)–metal titrations are described[3]. The aqueous phase of the acidified reaction mixture was separated from the benzene and made up to 5·00 ml. with water washings.

One µl. of the diluted reaction mixture was submitted to paper electrophoresis on Whatman No. 3 paper. The conditions of this and all subsequent electrophoresis runs were as follows: electrolyte, 0·025 M phthalate buffer, *p*H 5·9 (ref. 4); ambient temperature; 13 V/cm; time, 4 h. The apparatus used was of the closed strip type as described by Block *et al.*[5]. Autoradiographs were prepared using 'No-screen' X-ray film. The delineated spots were quantitized by counting with an end-window Geiger tube.

The apparent electrophoretic mobilities of the compounds resulting from the reaction of DET with bromoacetate are shown in Table 1. Under the conditions of the experiment, the separation of all the components was remarkably clear cut.

Table 1. APPARENT ELECTROPHORETIC MOBILITY OF COMPOUNDS RESULTING FROM THE REACTION OF DIETHYLENE-TRIAMINE WITH BROMOACETATE

Compound*	Mobility, cm (±)
DTPA	12 5–16·0 (+)
DTTA	10·8 (+)
DTTriA	0
DTDA	3·6–6·8 (—)
DTMA	10·0 (—)
Glycolate	5·2–8·2 (+)
Bromoacetate	0 5–1·3 (—)

* DTTA, diethylenetriaminetetraacetate; DTTriA, triacetate; DTDA, diacetate; DTMA, monoacetate.

The quantitative distribution of radioactive products formed in the first reaction is given in Table 2.

Table 2. QUANTITATIVE DISTRIBUTION OF RADIOACTIVE COMPOUNDS RESULTING FROM THE REACTION OF DIETHYLENETRIAMINE WITH BROMOACETATE

	First reaction			Second reaction	
Compound*	Per cent of total activity on electrophoretogram	Per cent No. of CO_2H	mmoles present	Per cent of total activity on electrophoretogram	mmoles present
DTPA	18·0	3 6	0·011	76·0	0·051
DTTA	2·4	0 6	0 002	12·7	0·009
DTTriA	5·0	1·7	0·005	0	0
DTDA	6·5	3·3	0·010	0	0
DTMA	10·8	10·8	0·032	0	0
Glycolate	4·0	4·0	0·012	11·3	0·038
Bromoacetate	53·3	53·3	0·160	trace	trace

*See Table 1.

Because of the incomplete conversion of reactants to DTPA, a second reaction was carried out using inactive bromoacetate (0·6 mmole) and the crude products from the first reaction; this was allowed to stand at room temperature for 16 hr. The unreacted bromoacetic acid was removed by ether extraction. After electrophoresis, the quantitative distribution of products was found to be as shown in Table 2.

DTPA-^{14}C was obtained in 96 per cent purity (determined by electrophoresis) by chromatography on 'Dowex-50' using water for elution. The specific activity was 4·8 mc./mmole.

Self-sustained Discharge Detector for Gas Chromatography

IN a recent communication to *Nature*, Drs. Evrard, Thevelin and Joossens[1] described their experience with a self-sustained discharge detector for chromatographic analysis of permanent gases. Argon containing 200 p.p.m. of ethylene was used as carrier gas, a mixture similar to that described elsewhere by Willis[2] for detecting atmospheric gases with an ionization detector containing a radioactive source. In both these methods, permanent gases quench the current flowing in the detector.

In their summary of the literature concerning the use of non-radioactive, electric discharge detectors, Evrard *et al.* state the belief that a concentration of organic vapour must be present if a self-sustained discharge is to be excited in argon. This is contrary to our experience.

In work reported by us previously[3], a stable, self-sustained discharge was excited in both argon and helium without the intentional addition of any contaminants. As would be expected, the voltage across an argon discharge was higher than the 500 V reported by Evrard *et al.* for the argon–ethylene mixture. The voltage varied between 1,600 and 1,900 V, depending on cell geometry, temperature and pressure, and fell to minimum levels of 500 V in the presence of organic vapour. The sensitivity of this discharge to organic vapours suggested its use as a detector for gas-liquid chromatography and it was so used with both polyester columns and silicone rubber columns at high temperatures and with silicone columns at room temperature, all with good effect. An analysis of fatty acid esters using a self-sustained argon discharge detector is shown in Fig. 1.

The argon used in these experiments was sufficiently free of organic contaminants to give a very low baseline current when used as carrier gas with a hydrogen flame ionization detector. While it may be argued that the gas-liquid column, even at ambient temperature, may provide a low concentration of organic vapours, the same argument cannot apply when well-conditioned gas-solid columns are used.

We have reported the sensitive detection of atmospheric gases in a self-sustained helium discharge[4]. Addition of small concentrations of each of the atmospheric gases caused an increase in the conductivity of this discharge. Wiseman, using a slightly different experimental approach, stressed the importance of purifying the helium prior to using it, but otherwise essentially confirmed our results[5].

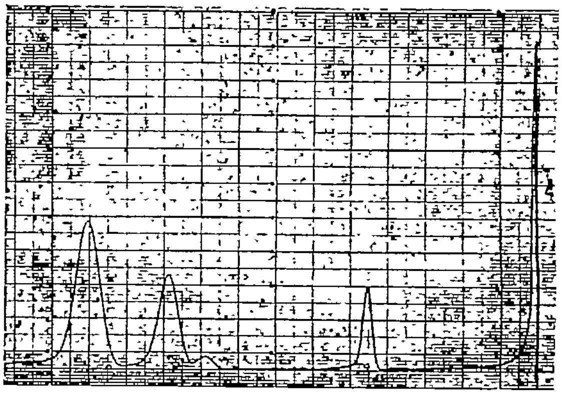

Fig. 1. Analysis of a mixture of methyl esters detected by an argon discharge. Total sample, 3 µg

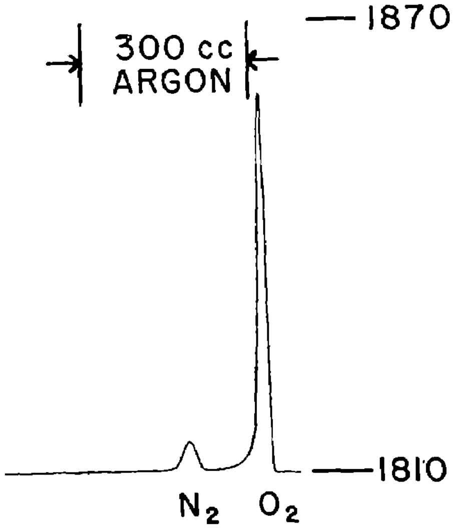

Fig. 2. Analysis of a 2 µl sample of air, analysed by a molecular sieve column, detected by an argon discharge

Since our experiments were performed using commercial helium without further purification, we interpreted our results as having been made possible by the care exercised to introduce as little atmospheric contamination to the gas stream as possible.

With the same equipment and the same care, we have also used argon as the carrier gas for the detection of atmospheric gases. Oxygen, nitrogen, and carbon dioxide each diminish the electrical conductivity of a self-sustained discharge in argon. The sensitivities of the discharge to carbon dioxide and oxygen are higher than that to nitrogen (Table 1) although not so high as the sensitivity to organic vapours. Fig. 2 shows the response of an argon discharge to a 2-µl. sample of air analysed by a molecular sieve column.

Table 1. SENSITIVITY OF THE ARGON DISCHARGE TO ATMOSPHERIC GASES

Gas	Sensitivity Increase in voltage across discharge for an increment in concentration of 1 vol. per million vol. argon
Oxygen	2·0
Nitrogen	0·06
Carbon dioxide	6·5

The high sensitivity of the argon discharge to oxygen in the absence of organic vapours suggests its potential utility for the detection of oxygen in argon–oxygen mixtures.

In both our previous reports on the use of the self-sustained discharge we described a mode of operation in which a constant current is passed through the discharge and the voltage across it measured. We have found this approach to be feasible whether the current is held constant within the limits of electronic regulation and the voltage across the discharge is measured directly or whether a large value resistor is used in series with the source of impressed voltage and the voltage across the discharge is indicated by the relatively limited changes in current. We prefer the first approach for two reasons:

(1) The voltage across a self-sustained discharge remains essentially constant in gas of constant composition despite moderate changes in current. The current, on the other hand, is a function of the series resistance as well as the impressed voltage. The voltage across the discharge thus serves as a better indicator of the gas composition.

(2) A self-sustained discharge, in our experience, is most stable over a limited range of current. It seemed, therefore, most desirable to keep the current at a value near the most stable part of that current range.

Constant current sources suitable for this purpose which provide a separate voltage signal proportional to the voltage across the discharge are now available commercially.

Wetting Phenomena in Gas Chromatography Capillary Columns

IN some instances poor efficiency with capillary columns has been reported, especially when glass capillaries were used. This may be due to two quite different phenomena : bad liquid-phase distribution on the smooth wall of the capillary caused by non-uniformity of radius, or non-wetting properties of the stationary phase. Giddings[1] has theoretically discussed the first reason; but experiments on it are lacking. This communication is concerned with the second point only. If the liquid phase does not spread on the wall, it coalesces into droplets: the larger these droplets the lower the efficiency. They may even come to plug the column, resulting in a saw-tooth gas flow pattern. The wetting properties of the stationary phase thus appear to be very important.

We have measured the contact angle θ of several usual liquid phases on metal, glass and polymer materials often used to make capillaries[2]. By plotting cos θ for a given substrate against the surface tension γ of the corresponding liquids one can obtain a maximum value γ_c compatible with spreading on this solid[3]. We have thus a means of evaluating both liquids and solids for use in capillary columns. Values of γ_c are given in Table 1.

It must be pointed out that this critical tension may vary with temperature, so that for a given liquid–solid pair a critical temperature may exist above which θ is zero[4]. This may explain some discrepancies in reported observations. Others may result from:

(*a*) The solvent used to deposit the stationary liquid film in the capillary. The solution may fail to spread on the wall, and another solvent should be sought. It is important to know that poor efficiency may result from non-spreading of the solution, even in cases where the liquid phase itself is capable of

Table 1

Solid	γ_c (dyne/cm)	Solid	γ_c (dyne/cm)
Stainless steel	24·0 ± 0·5	Polytetrafluoro-ethylene	19 ± 1
Aluminium	27·4 ± 0·5	Polyethylene	33 ± 2
Copper	27·0 ± 0·5	Polyethyleneglycol-terephtalate	40 ± 2
'Pyrex' glass* acetone washed	28·0 ± 0·5	Polyamide 6–6	41 ± 2
'Pyrex' glass* sulphochromic acid washed	44·0 ± 1·0		

* Values for 'Pyrex' are reproducible for a given cleaning method.

spreading; droplets of solution left behind when the column is emptied do not distribute evenly in a short enough time.

(*b*) Surface-active agents which may reduce surface tension of the liquid phase and thus facilitate the spreading of the liquid. The favourable effect of products like 'Alkaterge *T*' reported by Averill[5] may be due partly to this phenomenon.

(*c*) In general, roughening the wall of the capillary will decrease the contact angle and may be used to advantage.

(*d*) On the contrary other surface-active agents may be adsorbed on the surface of the capillary and in some cases reduce the solid–liquid adhesion. Owing to the viscosity, the slowness of coalescence may, however, give time for desorption of the surface active agent. Compounds of this kind may be expected mainly from the sample under analysis and, in spite of the small quantity present, may reach a concentration large enough to produce a local disturbance of the liquid film, travelling with the solute; a monolayer may be sufficient. This may produce a gradual alteration of the column with consequent loss of efficiency.

Measurements of contact angle and surface tension were made in air by photographing the profile of sessile drops. The nature of the carrier gas is not likely to alter appreciably the value of the critical tension.

We are extending this study to temperatures often met with in gas chromatography (50°–150° C).

We thank Miss M. Raison for some confirmatory measurements made by the dipping-plate method.

Unpaired Electron in Nitroso-*bis*(dimethyldithiocarbamato)iron(II)

We have examined the electron spin resonance spectrum of $[Fe(NO)\{S_2CN(CH_3)_2\}_2]$ to investigate how the unpaired electron, which is in an anti-bonding orbital in free nitric oxide, distributes itself in a metal complex. The magnetic moment of a powdered sample at room temperature is 2·24 B.M., which shows the complex to have one unpaired electron with an appreciable orbital magnetic moment. The electron spin resonance spectrum of a benzene solution consists of three equally intense lines with a separation of 0·0011 cm^{-1}. This triplet structure arises from an interaction between the unpaired electron and the nitrosyl nitrogen atom and indicates that the unpaired electron is in an orbital which embraces the nitrosyl group. This interaction is greater than that in free nitric oxide[1] in which the splitting is 0·00099 cm^{-1}.

Single crystals of this complex have also been studied by electron spin resonance and the dependence of the spectrum on the orientation of the crystal with respect to the field has been determined.

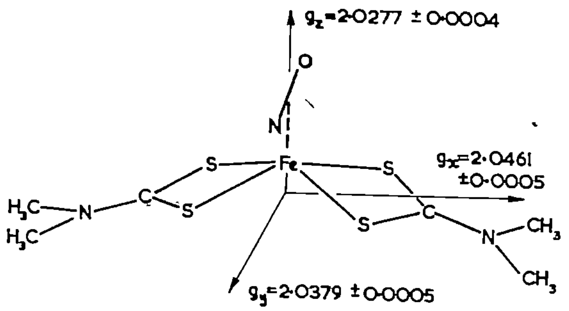

Fig. 1

Since the structure of the isomorphous $[Co(NO)\{S_2CN(CH_3)_2\}_2]$ is known[2] it is possible to determine from these results the directions of the principal *g* values with respect to the molecule. These are shown in Fig. 1. It is seen that the N—O direction is not important in determining the directions of the principal *g* values, as it would be if the unpaired electron were associated only with the nitric oxide ligand[3]. Instead the principal *g* directions are determined by the ligand field at the iron atom produced by the dithiocarbamate groups.

Our results indicate, therefore, that the unpaired electron is not entirely on the nitrosyl group, but is in a molecular orbital which includes both the iron atom and the nitrogen atom of the nitrosyl group, and which has the symmetry of the environment of the iron atom. Further experiments with more sensitive apparatus are planned to investigate whether the unpaired electron is also associated with the sulphur atoms.

BIOCHEMISTRY

Chemistry of a Case of Juvenile Amaurotic Idiocy

Chemical analysis which would give a hint of the nature of juvenile amaurotic family idiocy is still lacking. The condition is considered to be a metabolic disorder because of the abnormal intracellular deposits in the ganglion cells. Klenk[1] found no increase in the total amount of gangliosides; but Cumings[2] reported an increase in the neuraminic acid level in the cortex in adult cases of amaurotic family idiocy. Tingey[3], in his routine carbohydrate analysis of the brain of the present case (a 15-year-old boy), found no increase in neuraminic acid and no significant abnormality. The present investigation was conducted primarily to examine the nature of the glycolipids and polysaccharides present both in the brain and the liver.

The method used to fractionate the liver was a modification of that previously used[4] in an investigation of glycogen storage disease. In the present case extraction with M sodium chloride and cold N sodium hydroxide failed to extract any detectable glycogen. The very small amount present was presumably protein-bound and required hot 30 per cent potassium hydroxide for its extraction (cf. with normal liver[5]).

It was significant that no storage of uronic acid containing mucopolysaccharides was encountered in the liver. In fact, except where the 30 per cent potassium hydroxide procedure[6] was applied directly to the defatted tissue, no uronic acid was found in any polysaccharide fraction. In that instance the uronic acid was accompanied by glucose, mannose, galactose, and hexosamine in the laevorotatory (– 40°) polysaccharide mixture.

The major carbohydrate-containing macromolecules isolated were: (*a*) a mucoprotein $[\alpha]_D$ – 53° containing 23·5 per cent hexoses (galactose, mannose), hexosamine and 16 amino-acids; (*b*) a neutral mucopolysaccharide containing 44·3 per cent hexoses (glucose, galactose, mannose) and galactosamine; (*c*) an acidic polymeric carbohydrate sulphate $[\alpha]_D$ + 42° containing 26·9 per cent galactose and hexosamine; (*d*) an acidic polymeric carbohydrate sulphate $[\alpha]_D$ – 47° containing 10·2 per cent hexoses (glucose, galactose, mannose) and hexosamine.

The fractionation of both the grey and white matter of the brain was carried out by identical procedures. The acetone-dried tissues[7] were extracted with chloroform-methanol[8] and the crude lipids extracted, partitioned with water to separate out in the water phase a soluble non-dialysable fraction which consisted of those mucolipids of the ganglioside type which contained neuraminic acid. The chloroform phase, constituting the so-called total extracted lipids (Table 1), was successively fractionated on florisil[9] (to absorb phospholipids), and ion-exchange resins[9] (to absorb sulphatides) to leave a mixture of cerebrosides and cholesterol.

Table 1. COMPOSITION OF THE WHITE AND GREY MATTER (g/100 g fresh tissue)

	Cortex	White matter
Water	82·92	73·32
Total solids	17 08	26·68
Total extracted lipids ($CHCl_3$-MeOH soluble)	6·20	12·46
Total phospholipid	2·87	5·10
Cholesterol (free)	1·13	2·65
Cholesterol ester	0·10	0·19
Cerebrosides	0·91	2·17
Sulphatides	0·16	0·41
Water-soluble non-dialysable lipids	0·094	0 019

The carbohydrate content of the grey matter ganglioside (18·15 per cent neuraminic acid, 22·67 per cent hexose and 8·87 per cent hexosamine—mostly galactosamine) approximated more to that of a gargoylism ganglioside isolated by Svennerholm[10] (24·1 per cent neuraminic acid, 24·6 per cent hexose and 11·6 per cent galactosamine) than to that of the mucolipid isolated from a normal brain by Rosenberg and Chargaff[11] (21 per cent neuraminic acid, 33 per cent hexose, and 4·4 per cent *N*-acetylgalactosamine). Klenk and Gielen[1] have reported that ganglioside preparations are mixtures of at least three different components. Recently[12] other workers have reported different neuraminic acid : galactosamine ratios in fractionated gangliosides. It could well be that in juvenile amaurotic idiocy the proportion of the different gangliosides changes. In both the grey and white matter only galactocerebrosides were encountered. Phosphoinositides, phosphatidyl serine, phosphatidyl ethanolamine and phosphatidyl choline were indicated from a chromatographic examination of the grey and white matter total extracted lipids. In comparison with that of a normal 12-year-old child (Cumings *et al.*[13]) the phospholipid, cholesterol, and cerebrosides were all depleted in the present case. The insoluble residues remaining after lipid extraction contained small amounts of neuraminic acid and hexosamine but no evidence was obtained of preferential extraction of mucoprotein or mucopolysaccharide.

We thank Dr. R. M. Norman and colleagues of the Burden Neuropathological Laboratory, Frenchay Hospital, Bristol, for supplying the brain and liver, and the British Council for the award of a scholarship to one of us (S.H.I.B.).

Fibre Composition of Tough and Tender Muscles of Meat Animals

THE connective tissue content of muscles has been considered to be the principal biochemical entity responsible for toughness in meat. Little attention seems to have been given to the contribution which differences in the composition of muscle fibres themselves might make in rendering a muscle tough. I have examined the distribution of nitrogen within characteristically tough (semitendinosus) and tender (longissimus dorsi) muscles of different species (cattle, lambs, and pigs). The nitrogen components estimated were sarcoplasmic protein nitrogen, myofibril protein nitrogen, stroma nitrogen (by difference) and non-protein soluble nitrogen. The analytical technique used was essentially that of Lawrie's modification[1] of Helander's extraction technique[2].

Table 1 shows the average nitrogen distribution on a fat-free basis in the longissimus dorsi muscles at the 11th and 12th ribs and in the semitendinosi muscles in 8 Hereford Shorthorn bullocks (slaughtered at 32 months of age), 8 lambs of various crosses (age range 8–15 weeks) and 2 bacon weight pigs. Table 2 shows the data of Table 1 calculated on a stroma nitrogen-free basis.

The results show that the stroma nitrogen content is highest in beef muscles and lowest in pig muscles. Also beef muscles have the highest percentage of myofibril nitrogen on a stroma nitrogen-free basis. While the greater toughness of beef semitendinosus compared with beef longissimus dorsi is no doubt principally due to its higher content of stroma nitrogen, it does not seem unreasonable to suggest that, on a stroma nitrogen-free basis, the greater myofibril nitrogen content and smaller sarcoplasmic nitrogen content are to some extent reflected in the greater toughness of the semitendinosus. Extending this argument, it could be suggested that the greater

Table 1. Average Nitrogen Distribution on a Fat-free Basis in Muscles of the Three Species

		Percentage fat-free total nitrogen	Nitrogen components (% of total nitrogen)			
			Sarcoplasmic	Myofibril	Stroma	Non-protein soluble
Longissimus dorsi at 11th and 12th ribs	Cattle	3 89	19·12	54·73	13·62	12 53
	Lambs	3 40	25·56	54·05	8·09	12·31
	Pigs	3·80	23·64	56·71	7·24	12·41
Semitendinosi (distal end)	Cattle	3·79	16·03	55·68	16·94	11·35
	Lambs	3·26	24·44	52 24	11·37	11·95
	Pigs	3·47	21·67	56·87	9·08	12·89

Table 2. Average Nitrogen Distribution on a Fat-free and Stroma Nitrogen-free Basis in Muscles of the Three Species

		Percentage fat-free total nitrogen	Nitrogen components (% of total nitrogen)		
			Sarcoplasmic	Myofibril	Non-protein soluble
Longissimus dorsi at the 11th and 12th ribs	Cattle	4·50	22 13	63·36	14·51
	Lambs	3·70	27·81	58·81	13·89
	Pigs	4·10	25·49	61·14	13·38
Semitendinosi (distal end)	Cattle	4·56	19·30	67·04	13 66
	Lambs	3·68	27·58	58·94	13·48
	Pigs	3·82	23·83	62·55	13·68

sarcoplasmic and smaller myofibril nitrogen contents of lamb and pig muscles, when compared with beef muscles, are reflected to some degree in the greater tenderness of the muscles of these two species.

Ribonucleic Acid Synthesis in Chloramphenicol-treated *Shigella*

Chloramphenicol markedly inhibits protein synthesis by bacteria. The organisms, however, continue to produce ribonucleic acid (RNA) at an unaltered rate or at one higher than that of cells not under the influence of the drug[1,2]. Several groups of investigators have examined extracts of chloramphenicol-treated *Escherichia coli* to determine the cellular fraction in which the newly formed RNA was located. Pardee *et al.*[3] concluded from their findings that the RNA was either of a low molecular weight or was easily degraded during extraction from the cells. The latter explanation appears likely since the authors did not extract the RNA with a medium containing magnesium ions to minimize the breakdown of ribosomal particles. Using such a medium, Dagley and Sykes[4] and Nomura and Watson[5] detected the appearance of a new ribosomal component in the extracts of treated cells. The latter investigators also noted that soluble or low-molecular-weight RNA continued to be synthesized in the presence of the antibiotic.

In this laboratory, it was earlier observed that chloramphenicol stimulated RNA synthesis in resting cells of *Shigella flexneri* serotype 3[6]. Cell extracts of untreated and chloramphenicol-treated cells have been examined to determine whether the formation of soluble and/or ribosomal RNA was stimulated by the drug.

Strain *B*-1003 of *S. flexneri* serotype 3 was used. The organism was grown in a chemically defined medium[6]. Collected cells were washed in 0·01 M *tris* buffer (*p*H 7·4) containing 0·01 M magnesium acetate. To obtain resting cells, the organisms were resuspended in buffer, aerated to deplete endogenous nutrients, centrifuged, and stored overnight at 5° C. The cells were then washed in the buffer, resuspended in the defined medium, and equal portions added to each of three flasks. One flask of cells serving as a 0 h, or un-incubated, control was immediately centrifuged at 0° C in a Sharples supercentrifuge. Chloramphenicol was added to the second flask to give a final concentration of 2 μg/ml.; the third flask was used as a chloramphenicol-free control. The latter two flasks were incubated at 37° C for 4 h and the cells were then collected on the Sharples supercentrifuge. The packed cells were disrupted by grinding with alumina. Soluble and ribosomal RNA were separated by centrifugation at 100,000*g*. The RNA content of the soluble fraction was determined by the orcinol reaction and that of the ribosomal fraction was calculated as the difference between the total and the soluble fractions.

As shown in Table 1, the synthesis of soluble RNA was appreciably stimulated by chloramphenicol. In contrast, the level of ribosomal RNA synthesis was similar to that of the untreated cells. Thus chloramphenicol-treated cells exhibited a low ribosomal RNA/soluble RNA ratio. It should be pointed out that although the level of RNA synthesis varied among different cell preparations, the ribosomal RNA/soluble RNA ratios were similar in the various experiments. The cell wall and membrane fraction of the disrupted cells were also examined. The RNA content of this fraction from untreated and treated cells was less than 0·5 per cent of the total RNA and did not increase during incubation.

Table 1. Effect of Chloramphenicol on RNA Synthesis by Resting Cells of *Shigella flexneri* Serotype 3

Cell preparation	Cell fraction	Experiment 1			Experiment 2		
		RNA content*	Net increase	Ribosomal : soluble	RNA content	Net increase	Ribosomal: soluble

	Soluble	48	32		76	43	
	Total	147	72	2·1 : 1	226	119	2·1 . 1

* Expressed as mμM RNA nucleotide/ml. cells.

The significance of these findings from the point of view of the mechanism by which chloramphenicol inhibits protein synthesis is not as yet evident. It appears that the drug stimulates the production of soluble, but not ribosomal, RNA in *S. flexneri* serotype 3. Alternatively the results may indicate that the drug effects a degradation of ribosomal RNA in the cells or prevents the assembly of newly formed ribosomal RNA subunits. Either of these proposed activities could be the result rather than the cause of the blockage of protein synthesis by the antibiotic. A study of the biological activity of the soluble RNA formed by chloramphenicol-treated cells is being carried out.

This work was carried out under the sponsorship of the Commission on Enteric Infections, Armed Forces Epidemiological Board, and financially supported by the Surgeons General, Department of the Army and Department of the Navy.

Mechanism of the Ether Activation of Phospholipase *A*

IT has recently been shown that with many phospholipases the rate of reaction is appreciably influenced by the electrokinetic state of the enzyme and its substrate. Thus the lecithin-splitting activity of the phospholipase *B* of *Penicillium notatum* requires a negative ζ potential on the substrate's surface before activity commences, while the phospholipase *C* from *Cl. perfringens* needs a negatively charged enzyme and excess positive groups on the substrate[1,2]. On the other hand, the triphosphoinositide phosphomonoesterase of brain[3] requires the negative ζ potential of the substrate to be considerably reduced before activity can begin at an appreciable rate.

The physico-chemical characteristics of a phospholipase *A* reaction in an aqueous system have now been investigated particularly in respect of the ether activation reported by many workers[4]. The enzyme was purified by density gradient electrophoresis of cobra venom (*Naja naja*) using a glycerol gradient The preparation had an isoelectric point of about 5·1 and was electrophoretically homogeneous. The ovolecithin substrate was purified by chromatography on alumina and silicic acid columns. Phosphatidyl ethanolamine was prepared from egg yolk phospholipid by silicic acid chromatography. Analysis[5] showed it to contain about 90 per cent phosphatidyl ethanolamine, the remainder being ethanolamine plasmalogen and the saturated ether analogue.

The enzyme was assayed in an aqueous system[4] in which the substrate was emulsified in buffer and the decrease of acyl-ester groups recorded on incubation. Ca^{++} was found to be obligatory for the attack on both substrates and was used throughout at a concentration of 5 × 10^{-4} N. Addition of 10 per cent by volume of ether enormously activated the hydrolysis of lecithin. However, it was unexpectedly found that the activity of the enzyme towards phosphatidyl ethanolamine was unaffected and often slightly inhibited by the addition of this solvent.

Measurements of the electrophoretic mobility of lecithin particles[1] in *p*H 6 5 collidine buffer containing 5 × 10^{-4} N Ca^{++} showed them to be slightly negatively charged. On incubation with enzyme at 30°, there was a small increase in the mobility consistent with the release of a small quantity of fatty acid and consequent appearance of carboxyl groups in the organized surface of the lecithin micelle. However, when ether was added to saturate the buffer (10 per cent by volume) incubation with the enzyme caused virtually no change in the electrophoretic mobility of the lecithin particles, in spite of the liberation of greatly increased amounts of fatty acid and lysolecithin. It was found, furthermore, that artificially produced mixed micelles containing lecithin, lysolecithin and fatty acid were very negatively charged in collidine buffer and that this charge was reduced almost to zero by the addition of ether. Addition of fatty acid to lecithin micelles produced inhibition of the enzyme system, even in the presence of ether when very few of their carboxyl groups appeared on the surface.

It is suggested, therefore, that the enzyme, which is negatively charged at this *p*H (6·5), attaches itself to negative sites on the lecithin micellar surface by a calcium bridge. Such sites may be those tertiary acidic groups of the phosphate moieties of the lecithin which are not compensated by the quaternary ammonium groups of the choline. The appearance of carboxyl groups on the surface of the micelle competes with these negative sites for the Ca-enzyme$^+$ complex, and the reaction is suppressed Ether causes a reorganization of the micelle so fatty acid carboxyl groups are no longer present on the surface, or, alternatively, it removes the fatty acid from the substrate micelles entirely. In agreement with this theory, the addition of a long-chain anion to the lecithin (dicetylphosphate or dodecyl sulphate) caused inhibition of the ether activated system and at the same time produced a negative ζ potential on the substrate. No reversal of the inhibition was obtained on addition of cetyltrimethyl ammonium bromide to these particles in sufficient quantities to reverse the charge and produce a positive ζ potential.

Phosphatidyl ethanolamine micelles are negatively charged at *p*H 6·5 and this charge increases with increasing *p*H, presumably due to the suppression of the ionization of the amino group. Correlated with this liberation of free tertiary acidic groups of the phosphate moiety on the substrate's surface is an increase in the rate of enzymatic hydrolysis up to *p*H 9·3. In contrast lecithin, the mobility of which does not change appreciably between *p*H 6 and 10, does not show a similar increase in enzymatic hydrolysis with increasing *p*H. On incubation of phosphatidyl ethanolamine with enzyme at *p*H 9·3, it becomes only very slightly more negatively charged even when the reaction has gone to 50 per cent completion. This suggests that the fatty acids liberated are not being orientated in the micelle–water interface, perhaps because of repulsion by the large excess of negative charges on the surface. Addition of ether to the system only reduces the negative charge of phosphatidyl ethanolamine particles very slightly and those of the substrate after incubation by the same amount. It would seem, therefore, that this substrate has many more negative sites available for the attachment of the Ca-enzyme$^+$ complex and can more -

adequately compete with the few carboxyl groups which appear on the surface as the reaction proceeds. Consequently ether has no activating effect. In contrast when mixed micelles of phosphatidyl ethanolamine and fatty acid are prepared artificially the negative charge of such particles is much higher than that of the phospholipid alone. This indicates that, in this case, carboxyl groups are present on the surface and, in agreement with this, it is found that the enzymatic hydrolysis of the substrate is inhibited by the presence of the fatty acid.

To summarize, it is suggested that a phospholipase *A*-calcium complex links with anion sites (phosphate) on the surface of the lecithin micelle. The carboxyl groups of the fatty acids liberated in the reaction appear to a limited extent in the micelle–water interface, and inhibit the reaction by competing with the anion sites for enzyme. Saturation of the system with ether removes carboxyl groups from the surface and the reaction can proceed. With phosphatidyl ethanolamine micelles, there are many more free anion sites on the surface. The few carboxyl groups appearing on the surface as the reaction proceeds only have a very limited competing effect and consequently ether does not activate.

Positional Specificity of Phosphatide Acyl Hydrolase (Phospholipase *A*)

SNAKE venom phospholipase *A* was shown by de Haas and van Deenen to release the fatty acid constituent present in the β-ester position of mixed-acid phospholipids obtained by a synthesis *de novo*[1–3]. This result confirmed those of Tattrie[4] and Hanahan *et al.*[5], who worked on fatty acid distribution in egg lecithin, using phospholipase *A*, phospholipase *D* and pancreatic lipase. Hence, the positional specificity of phospholipase *A* appeared to be settled. Recently Bennett and Tattrie[6], however, reported, because of reacylation investigations of snake-venom-formed lysolecithin, that this enzyme may not invariably hydrolyse the β-fatty acid ester bonds. This assumption supports the interpretation previously made by Marinetti *et al.*[7], indicating a preference of the enzyme for liberating long-chain poly-unsaturated fatty acids, irrespective of their position in the phospholipid molecule. For this reason further investigations into the mode of action of phospholipase *A* were made.

The synthetic lecithins and cephalins investigated so far by us contained either two dissimilar saturated fatty acid constituents or one saturated and one mono-unsaturated fatty acid of equal chain-length in different positions. In view of the conflicting opinions, a further check on the specific action of phospholipase *A* required examination of phospholipids containing, in different positions, a poly-unsaturated fatty acid with a chain-length dominating that of the saturated fatty acid constituent. The synthesis of mixed-acid lecithins and cephalins, involving the preparation of defined γ,β-diacylglycerol iodohydrins, has already been published[8,9]. In the present investigation (γ-linolenoyl-β-palmitoyl)-L-α-phosphatidyl ethanolamine and (γ-palmitoyl-β-linolenoyl)-L-α-phosphatidyl ethanolamine were prepared by a coupling of the corresponding mixed-acid γ,β-diacylglycerol iodohydrins with silver benzyl-2-ethyl-phthalimido phosphate, as previously described[10]. Experimental results of the synthesis of phospholipids with polyenoic acyl chains will be described elsewhere. Emulsions of 10 mg of both structural isomeric phospholipids, prepared in 1 ml. of borate buffer, pH 7, calcium chloride $2 \cdot 5 \times 10^{-3}$ M, with a few drops of ether, were incubated together with 2 mg of snake venom (*Crotalus adamantheus*) for 6 h at room temperature. The entire reaction mixture was lyophilized and adequate samples dissolved in chloroform were subjected to chromatography on silica-impregnated paper according to Marinetti[11]. The paper chromatogram demonstrated a complete breakdown of both substrates. The spots of the liberated fatty acid and formed lysophospholipid were treated directly with methanol/hydrochloric acid, and the fatty acid methylesters thus obtained were analysed by gas-liquid chromatography.

Table 1 ACTION OF PHOSPHOLIPASE *A* ON TWO SYNTHETIC MIXED ACID L-α-PHOSPHATIDYL ETHANOLAMINES, CONTAINING LINOLENI ACID IN DIFFERENT MOLECULAR POSITIONS

Substrates	Fatty acid composition afte hydrolysis by phospholipase *A*	
	Liberated fatty acid	Lysophospholipid
(γ-Palmitoyl-β-linolenoyl)-L-α-phosphatidyl ethanolamine	98·5 per cent linolenic acid	99 per cent palmitic aci
(γ-Linolenoyl-β-palmitoyl)-L-α-phosphatidyl ethanolamine	97 per cent palmitic acid	97·5 per cen linolenic aci

The results obtained (Table 1) showed that during the enzymatic hydrolysis of both synthetic phospholipids, the β-fatty acid is liberated, thus confirming our previous conclusions. It should be noted that th results presented here have not been corrected for non-enzymatical 'at random' degradation, which wa shown to occur to a very small extent under the condi tions used. The experiments did not reveal a prefer ential enzymatic release of the long-chain poly unsaturated fatty acid constituent, and hence do no support the reports[6,7] attributing a lack of position specificity to snake-venom phospholipase *A*. I addition, it should be pointed out that experiments o the phosphatide-(mono)acyl hydrolase from be venom and pancreas demonstrated that thes enzymes also exhibit a β-specificity for synthetic phos pholipids.

PHYSIOLOGY

Electrophoretic Mobility of Serum Post-heparin Tributyrinesterase

MUCH work has been devoted to the mechanism of the clearing action of heparin, and it is now generally accepted that its action is exerted by a lipolytic enzyme called clearing factor. On the other hand, it has been found that the injection of heparin is followed by the appearance in the serum of an eserine-resistant tributyrinesterase, which is considered to be one and the same with clearing factor[1]. Various techniques were used to locate the clearing factor in the serum protein fractions, including fractional precipitation[2] and ultracentrifugal fractionation methods[3]. The findings of the different investigators are not in agreement. Thus, it has been claimed that clearing factor remains in the albumin fraction of serum after half saturation with ammonium sulphate[2]. However, Graham *et al.*, using ultracentrifugal and ethyl alcohol fractionation, found the enzyme in the globulin fraction[3]. Because of this discrepancy, investigations were made in order to study the electrophoretic mobility of the clearing factor (post-heparin tributyrinesterase[1]) in comparison with the fractions of the proteinogramme.

Our investigation was carried out under the following conditions: A volume of 0·04 ml. serum was applied in a linear fashion to a Whatman No. 3 paper strip. Electrophoresis was carried out in an Elford apparatus at 4° C temperature, in a veronal buffer ionic strength 0·05 and *p*H 8·6 for 9 h. The distribution of the enzymes on the paper strip was examined after electrophoresis by the following procedure: The strip was divided into two other strips of 1·5 cm and 3 cm width. The first was dried and stained with bromophenol-blue in order to obtain the electrophoretic pattern of serum proteins, and afterwards was used as a marker. The other strip, immediately after electrophoresis, was cut up into 1-cm pieces while still wet. These pieces were transferred to small test-tubes containing 1·0 ml. of distilled water. They were allowed to stand for 12 h at a temperature of 4° C. To each of the eluates the tributyrinesterase activity was measured, by Tuba–Hoare's method[4], with some modifications, as follows. 1 ml. of veronal buffer *p*H 8·6 and 0·03 ml. of glycerol tributyrate was added to each tube and after vigorous shaking the mixtures were incubated for six hours at 37° C. The enzyme action was finally stopped by adding 4 ml. of alcohol. The tubes were then centrifuged and the butyric acid content of supernatant was measured by titration with sodium hydroxide (0·025 N) using phenolphthalein as indicator. The tributyrinesterase activity of the eluates was reported to the serum protein fractions of the bromophenol stained strip (marker).

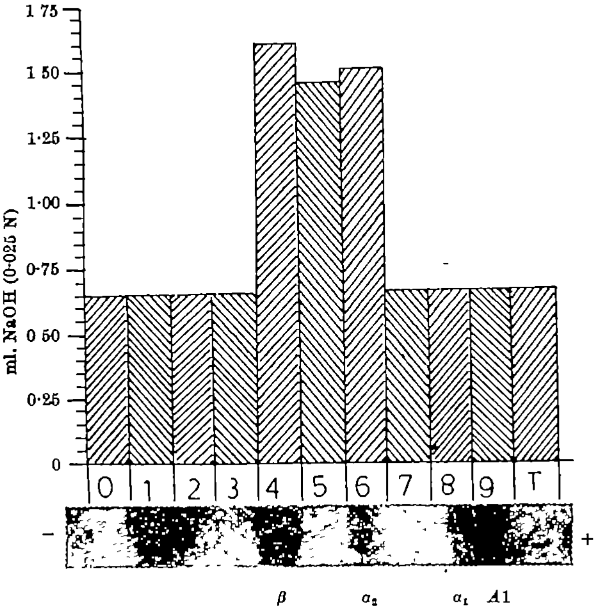

Fig. 1

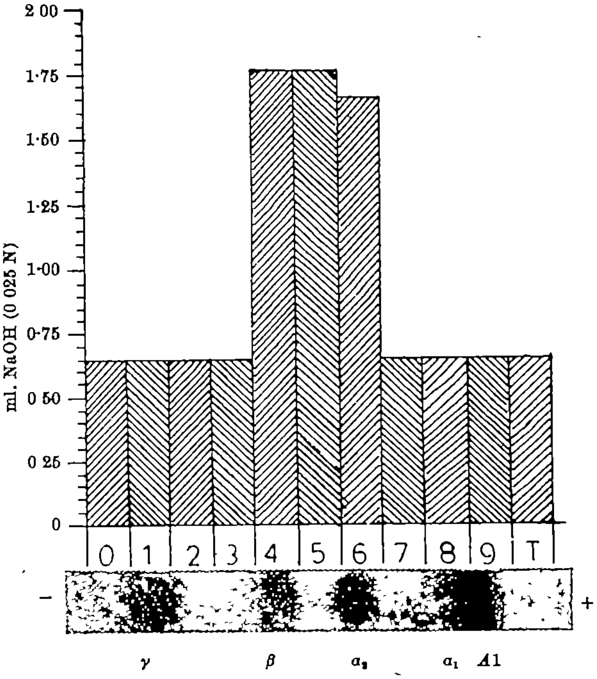

Fig. 2

In a preliminary series of experiments the electrophoretic mobility of normal serum tributyrinesterases was studied in sera received from 20 non-heparin-treated normal individuals. In a second series of experiments the electrophoretic mobility of post-heparin tributyrinesterase was studied in sera received from 10 healthy subjects 5 min after intravenous injection of 2·000 units of heparin.

These sera were centrifuged for 30 min at 3,000*g*/min in order to remove the platelets and leucocytes[5]. They showed a definite increase in tributyrinesterase activity (about 20 per cent) in comparison with the sera of the same subjects received before injection.

The results of our preliminary experiments are presented in Fig. 1. It is evident that tributyrinesterase activity was found on the paper pieces corresponding to the zone defined from the anode side of the α_2-globulin fraction and the cathode side of β-globulin fraction. In Fig. 2 are presented the results from the electrophoretic study of post-heparin sera. It is evident here that tributyrinesterase activity was recovered both in the α_2-globulin and β-globulin fractions and in the zone in between. No enzymatic activity was recovered in the albumin, α_1- or γ-globulin fractions.

It can be concluded, therefore, that serum post-heparin tributyrinesterase is an α_2- or β-globulin and has an electrophoretic mobility identical to this of normal serum tributyrinesterases.

Our conclusion is in agreement with the ultracentrifugal and ethyl alcohol fractionation findings of Graham *et al.*[3].

The heparin used in our experiments was kindly supplied by Boots Pure Drug Co., Ltd.

Capillary Blood Standard Bicarbonate Values of Conscious and Anæsthetized Individuals

THE clinical significance of blood standard bicarbonate has not yet been firmly established. Relatively little information is available at present concerning the effect of surgical anæsthesia on this new parameter in capillary or arterial blood. Payne and Conway[1] recently concluded that normal values for arterial blood standard bicarbonate were significantly lower than those reported by Astrup *et al.*[2] on capillary specimens. The latter workers contend that comparable standard bicarbonate values are obtained from arterial and capillary blood. Evaluation of acid-base balance during anæsthesia in our hospital revealed that standard bicarbonate concentrations of capillary blood from conscious and anæsthetized subjects were consistent with those of Astrup *et al.*[2].

Capillary blood collected from 15 clinically healthy medical students, analysed in Astrup equipment, yielded an average standard bicarbonate of 23·4 ± 1·6 m. equiv./l. The value is close to the mean (22·9 ± 1·5 m. equiv./l.) quoted by Astrup *et al.*[2] for capillary blood of 65 apparently normal persons. In line with these findings, Robinson[3] observed average standard bicarbonate-levels of 24·4 m. equiv./l. in arterialized venous blood of 20 fit males. Likewise, Papadopoulos and Keats[4] noted a mean arterial standard bicarbonate-level of 24·7 ± 0·7 m. equiv./l. in 20 subjects prior to orthopædic or gynæcological surgery.

A total of 124 standard bicarbonate estimations were made on capillary blood taken from 24 patients before, during and following major surgery. Anæsthesia was maintained by orotracheal administration of *cyclo*propane, nitrous oxide or halothane, following induction with thiopental and succinylcholine. Ventilation was controlled both by manual and mechanical methods. Standard bicarbonate-levels during anæsthesia ranged from 18·5 to 28·5 (mean 22·9 ± 2·3 m. equiv./l.). Although a majority of values fell within normal limits reported by Astrup *et al.*[2], 20 were above 24·8 m. equiv./l. and 8 dropped below 21·3 m. equiv./l. In anæsthetized patients, Robinson[3] as well as Papadopoulos and Keats[4] observed means of 23·3 and 21·8 m. equiv./l., respectively. The latter figure obtained on arterial blood tends to approach the lower standard bicarbonate-level (18·14 ± 1·94 m. equiv./l.) found by Payne and Conway[1] also in arterial blood of 22 patients anæsthetized with halothane. Individuals studied by Papadopoulos and Keats[4], however, were subjected to prolonged hyperventilation during surgical anæsthesia. Available evidence indicates that a modest to moderate compensatory metabolic acidosis frequently accompanies respiratory alkalosis[5].

Capillary blood collected from 16 patients during the first 2 hours following surgery yielded a mean standard bicarbonate of 23·6 ± 2·2 m. equiv./l. (range 18·6–26·5). These data compare favourably with the average obtained on medical students. A similar relationship between control and post-operative standard bicarbonate-levels was noted by Payne and Conway[1]. A reasonable explanation for the low values reported by these workers may stem from the use of arterial rather than capillary specimens. Ideally, arterial blood should be used for acid-base evaluation, but the collection procedure is not without danger to the patient. Woolmer[6] suggests that under general anæsthesia there is sufficient vasodilatation to effectively arterialize capillary blood.

Effect of Potassium Depletion on Lactic Dehydrogenase Activity in the Rat Nephron

IN potassium depletion, the kidney is unable to concentrate the urine properly[1,2]. Striking morphological changes have been found in the region of the medulla and papilla[3,4,5]. In addition, marked changes in enzymatic activity, located mainly in the medulla, have been demonstrated by means of histochemical staining methods[6]. In the work reported here, lactic dehydrogenase activity was measured in various functional units of the kidney of normal and potassium-depleted rats through the use of the quantitative histochemical techniques originated by Lowry[7].

Male Sprague-Dawley rats, weighing between 100 and 150 g, were depleted of potassium over a 4-week period by feeding them a virtually potassium-free diet which contained a sodium polystyrene sulphonate resin and supplements of vitamins and minerals[8]. They drank a solution of 0·45 per cent sodium chloride and 0·45 per cent sodium bicarbonate. The test and control animals were pair fed. The controls were not given resin, while potassium chloride (50 m.equiv./l.) was added to the drinking water. Within three weeks the rats on the depletion diet became lethargic, lost weight, and developed a shaggy coat[8]. The mean serum potassium-level was decreased significantly from 5·7 m.equiv./l. (*S.E.* 0.41) for the control animals to 2·9 m.equiv./l. (*S.E.* 0·32) for the potassium-depleted group ($P = 0{\cdot}00027$). After urine was collected on sheets of sterile aluminium foil, the animals were anesthetized with ether, the abdomen was opened, and blood was drawn from the inferior vena cava for chemical analysis. A 2-mm. thick cross-section was cut from the right kidney, extending from the renal capsule to the papilla tip. It was mounted on a microtome sample holder and quickly frozen in liquid nitrogen. The tissue was sectioned at 16μ in a cryostat at −20° C, lyophilized and used for microdissection, as described previously[9,10]. The individual structural units of the nephron were identified by means of alternate stained sections and dissected out from the dry sections[10]. Both in the control and the potassium-depleted animals the loops of Henle in the inner medullary zone appeared dark and narrow in the dry sections ; the collecting ducts, light and broad. The nephron fragments were weighed on a quartz fibre 'fishpole' balance[11] and placed in a micro test-tube for the enzyme assay. The lactic dehydrogenase (LDH) assay has been described previously[12]. LDH activity in serum and urine was determined by the same assay method, diluting serum samples 1 : 100 and urine samples 1 : 10 with the substrate reagent.

LDH activities found in various parts of the nephron and in the serum and urine of the potassium-depleted and control rats are summarized in Table 1. Potassium depletion affected only the inner medullary zone (Table 1(*a*)). A significant increase of the LDH activity was noted in the collecting ducts of the inner medullary zone (287 versus 67 M/kg/h, P = 0·0382). A decrease in LDH activity which was not significant was seen in the loop of Henle (157 versus 219 M/kg/h, P = 0·0996). The experiment was repeated with a larger number of rats (Table 1(*b*)). Again a significant increase in LDH activity occurred in the collecting ducts of the inner medullary zone (273 versus 145 M/kg/h, P = 0·00529), and a decrease in the loop of Henle which was not significant (123 versus 156 M/kg/h, P = 0·0725).

Table 1. LACTIC DEHYDROGENASE ACTIVITIES IN THE KIDNEY, SERUM, AND URINE OF NORMAL AND POTASSIUM-DEPLETED RATS*

Material analysed	Control	Potassium-depleted	P†
(*a*) 4 weeks depletion :	[2]	[2]	
Glomerulus	71 ± 5·6 (12)	57 ± 8·2 (10)	
Proximal convoluted tubule	152 ± 8·1 (14)	137 ± 23 (12)	
Distal convoluted tubule	231 ± 18 (17)	232 ± 20 (12)	
Outer medullary zone	88 ± 26 (9)	101 ± 8·7 (12)	
Inner medullary zone, collecting duct	67 ± 4·6 (9)	287 ± 43 (10)	0·0382
Inner medullary zone, loop of Henle	219 ± 15 (10)	157 ± 15 (12)	0·0996
Papilla, collecting duct	196 ± 21 (14)	156 ± 12 (22)	
Small artery	66 ± 5·1 (9)	66 ± 5·0 (12)	
(*b*) 4 weeks depletion :	[4]	[4]

Inner medullary zone, loop of Henle	156 ± 13 (16)	123 ± 7·8 (16)	0·0725
Papilla, collecting duct	53 ± 3·4 (19)	62 ± 4·1 (29)	
(*c*) 2 weeks depletion :	[5]	[5]	
Serum	35·6 ± 5·1	36·5 ± 4·9	
Urine	0·14 ± 0·038	4·40 ± 2·3	0·1007
4 weeks depletion :			
Serum	51·3 ± 4·0	58·4 ± 10·0	
Urine	0·29 ± 0·095	0·79 ± 0·19	0·0463

* Results are given as mean values with the standard error of the mean, and in parentheses the number of tissue fragments analysed. Activities in the tissue fragments are expressed in moles of DPNH oxidized per kg dry weight per h incubation at 37° C. Activities in serum and urine are expressed in millimoles of DPNH oxidized per litre per h incubation at 37° C. Number of animals in each experiment is given in brackets.

† The bilateral probability P was calculated by means of Student's *t*-test with the number of degrees of freedom equal to the total number of animals less two. Only values of P = 0·10 or below are shown.

The results of these two experiments cannot be combined directly, because they represent experiments at different times with different groups of animals. However, the bilateral probabilities can be combined by the method of Fisher[13], using the formula :

$$\chi^2 = -2 \ln \frac{P_1 . P_2 . . . P_n}{2^n}$$

finding the combined probability from a table of χ^2, assuming $2n$ degrees of freedom and multiplying by 2 to obtain the bilateral probability P. For the collecting duct this gives a combined bilateral probability P = 0·0013 ; and for the loop of Henle, P = 0·026. It is concluded, therefore, that potassium depletion caused an increased LDH activity in the collecting ducts of the inner medullary zone and a decreased LDH activity in the loop of Henle.

The serum LDH-level remained unchanged at 2 and 4 weeks of potassium depletion (Table 1(*c*)). A considerable increase in urinary excretion of LDH was noted at 2 weeks of depletion. This change was still noticeable at 4 weeks of depletion ; the combined bilateral probability was P = 0·018. The increased urinary excretion of LDH may be related to the partial loss of this enzyme from the loop of Henle.

The primary structural lesion in the kidney of the potassium-depleted rat is mainly in the lower reaches of the nephron, in the medulla, especially in the collecting ducts[3,4]. The main functional effect of potassium depletion consists of an inability to concentrate the urine[1,2,4]. This is followed by conservation of potassium[14], which can probably be considered an adaptive response. A number of other enzymatic changes in the kidney have been reported in potassium depletion.

Muntwyler *et al.*[15,16] found increased activities for glutaminase and carbonic anhydrase in the whole kidney homogenates of potassium-depleted rats which were not protein depleted. After repletion for one week, they observed that these activities had almost returned to normal. They found no changes in the activities of *d*-amino-acid oxidase and arginase. By histochemical staining methods, Pearse and MacPherson[6] observed an increased activity of TPN-diaphorase in both limbs of the loop of Henle and in the papillary collecting ducts, as well as increased activities of acid phosphatase and phosphorylase in the papillary collecting ducts and of esterase in the proximal convolution and the pars recta. They also reported a decreased activity of TPN-diaphorase in the papillary collecting ducts. More recently, Davis[17] detected an increase in the pyruvate kinase activity in the medulla of the potassium-depleted rat. His observation of a much smaller increase in LDH activity is understandable in the light of our finding of opposite changes in different parts of the medulla, since he worked with a whole homogenate of the medulla.

It would seem that the histological changes in the medullary collecting ducts and the increased activities of glutaminase, carbonic anhydrase, TPN-diaphorase, acid phosphatase, phosphorylase, and pyruvate kinase in potassium depletion could all be part of an adaptive mechanism aimed at the conservation of potassium. The increased lactic dehydrogenase activity in the medullary collecting ducts described here fits into this pattern. Both LDH and pyruvate kinase play an important part in the cellular energy metabolism as a link between the glycolytic pathway, mainly located in the cytoplasm, and the Krebs tricarboxylic acid cycle, mainly located in the mitochondria. In view of the counter-current exchange between the loop of Henle and the adjacent collecting ducts[18], one could speculate that the simultaneous decrease of LDH activity in the loop of Henle might be part of the same adaptive response, aimed at the conservation of potassium[19].

Changes in Multilocular Brown Adipose Tissue in the Rat following Hypothermia

BROWN fat is involved in reactions to stress and in hibernation. The observations reported here show that it may also be altered in the rat after hypothermia. The Giaja closed jar technique was used for cooling and the method of Goldzveig and Smith for re-animation[1].

At autopsy 14–16 days after a single cooling to just below 2° C rectal temperature, hooded rats tended to have paler and less red interscapular brown fat than uncooled controls. The lobes lying dorsal to the submaxillary glands showed the same tendency. The experimental animals were still underweight (mean $=$ 165 g, $N = 14$) compared with the controls (mean $=$ 195 g, $N = 15$) at autopsy, but since there is evidence that the brown fat is darker and redder in states of food deprivation[2–4] and stress[5,6] it is unlikely that the colour differences found here were a simple function of the reduced food intake that follows hypothermia. Both groups of animals in this experiment had similar experience on a conditioned avoidance task.

In another experiment, growing male albino rats were repeatedly cooled to 2° C (Table 1). The finding of Andjus[7] that repeatedly cooled rats come to withstand hypothermia better was confirmed. 6–8 days after the last cooling the brown fat lobes dorsal to the submaxillary glands were dissected out. They were paler than those of controls and reduced in extent. Subsequent histology showed that there were marked changes. The homogeneous appearance of the sections was disrupted (Fig. 1). The white fat of cooled rats was also greatly reduced. Scarcely any was visible around the kidneys. Judged from this the animals would be considered to have been in a state of severe inanition. Yet their total body-weights were not far below those of controls (Table 1). Moreover, in another group of animals, the food of which was restricted so that their body-weights stayed below those of cooled animals, much more perirenal white fat was visible, and the lobes of brown fat sampled appeared histologically normal. This shows that the changes in the sections taken from cooled animals are not simply dependent on body-weight losses.

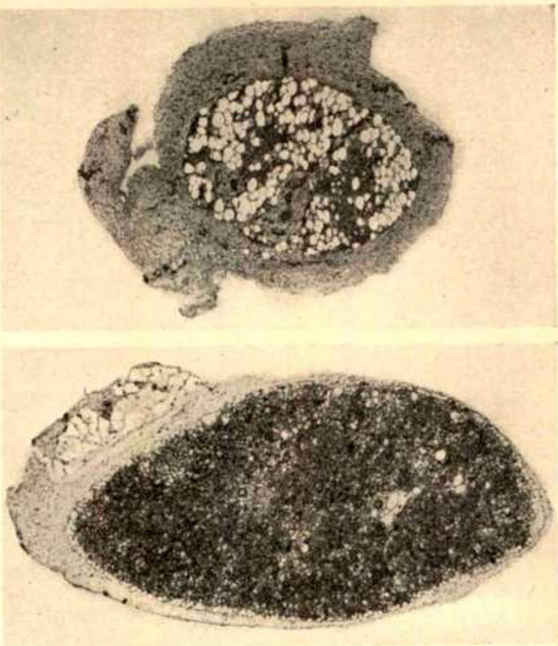

Fig. 1. Multilocular adipose tissue (× *c*. 28). Fixed in Bouin, stained with eosin and hæmatoxylin, cleared in xylol. Top, experimental (1 *P*7); bottom, control (2 *P*7)

The relative difficulty in reducing the brown fat has led to the theory that it is an ultimate reserve[8]. From the present results it seems that hypothermia can result in a selective utilization of adipose tissue including perhaps the brown fat reserve. Preliminary investigations have also shown that in a state o selective deposition of fat such as occurs in hypothalamic hyperphagia the brown fat is increased though histology will be necessary to determine whether this is due to an increase in multilocular cells or ordinary unilocular fat cells.

Table 1

Animal No.	Weight, 30th day	Treatment (30–64th day)	Weight at autopsy 70–71st day
3 *P*1	60	Cooled to 15 ± 1° C.	200
4 *P*1	84	6 ± 1° C., 3° C., 2° C.,	221
1 *P*7	57	2° C, 2° C, 2° C	229
2 *P*1	62		210
2 *P*7	57		237
3 *P*7	43		210
1	50	Controls	222
3	53		208
5	46		219
7	52		233
		31st–71st day	
2	53		180
4	43	Food restriction	181
6	50		185
8	52		171

The difference between the colour changes after hypothermia and food restriction suggests that brown fat may function as a special as well as an ultimate reserve. It has been found that in the hedgehog this tissue is particularly affected when animals emerge from hibernation[9]. It may be that recovery from artificially induced hypothermia provides circumstances for the utilization of brown fat in the rat that are normally lacking.

Experiments are in progress to determine whether these changes can be seen in other areas of brown fat, and with different temperature treatments.

I thank Dr. M. Khaïry and Dr. A. U. Smith for their help, and the Medical Research Council for supporting the work.

PHARMACOLOGY

Potentiation of the Effects of Indirect Sympathomimetic Amines by Reserpine and Bretylium

IT has been shown[1,2] that the effects of sympathomimetic amines, called indirect (tyramine, phenylethylamine, phenylethanolamine, ephedrine, amphetamine), are abolished by pretreatment with reserpine. However, immediately after an injection of reserpine, the effects of indirect sympathomimetic amines are potentiated[2,3]. On the other hand, it has been reported that bretylium enhances the effects of tyramine[4].

The object of the work recorded here is to try to differentiate the potentiating effects of reserpine and bretylium and, in addition, to find an eventual difference between some indirect sympathomimetic amines. We used the preparation of pithed rat prepared by Shipley and Tilden's method[5].

The hypertensive effects of phenylethylamine and amphetamine were greatly increased by small doses of reserpine, but those of phenylethanolamine and tyramine were augmented to a smaller extent. The threshold dose of reserpine potentiating phenylethylamine and amphetamine was 0·05–0·1 mg/kg, but the threshold doses for increasing tyramine and phenylethanolamine effects were greater (0·25 mg/kg). The potentiation disappeared rapidly with repeated injections.

This potentiating effect of reserpine was lost in the rat pretreated with large doses of reserpine (10 mg/kg intraperitoneal 24 h before the experiment), but could be obtained if *nor*epinephrine (0·05 μg) was injected at the beginning of the experiment.

Injection of 5 mg/kg of bretylium produced a hypertension and, after the return of blood pressure to the initial level, potentiated the tyramine effect, but did not increase phenylethylamine and amphetamine hypertension.

This potentiating effect of bretylium could not be obtained in the rat pretreated with large doses of reserpine. However, after administration of small doses of reserpine, bretylium still increased the tyramine hypertension, and the same is true of the reverse process.

These results show: (1) That the potentiating effects of bretylium and reserpine to the indirect sympathomimetic amines seem to be correlated to the presence of *nor*epinephrine in the body, but that the mechanisms of the two sensitizations are not exactly the same. (2) That the effects of indirect sympathomimetic amines depend on the presence of *nor*epinephrine in the body, but all the sympathomimetic amines do not act in exactly the same way.

To explain these results it is suggested that *nor*epinephrine is present in the body in several forms or in several storage areas and that these forms or storage areas are sensitive to the drugs in different ways.

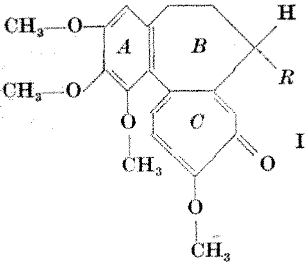
Desacetylamino-colchicine: a Derivative of Colchicine with Increased Cytotoxic Activity in Mammalian Cell Cultures

COLCHICINE, the main alkaloid of *Colchicum autumnale*, is well known for its action on the mitotic spindle, resulting in an arrest of mitosis in metaphase. The synthesis of derivatives of this compound is of interest for several reasons. Some were used to elucidate the chemical structure of colchicine. In addition, many of them were tested for their ability to inhibit the growth of tumours. Furthermore, such compounds made possible an analysis of relationships between structure and biological activity of the colchicine molecule. In earlier investigations of the relation between structure and activity it was demonstrated that compounds lacking the acetyl group on the side-chain may be equally as active as colchicine[1,2]. In addition, the methoxy group on the tropolone ring could be replaced by a free or substituted amino group without loss of biological activity[3].

Recent developments in the chemistry of colchicine[4] made available a number of nitrogen-free derivatives of colchicine. Of these, desacetylamino-colchicine (I) was of particular interest since its structure is identical with that of the parent compound, colchicine (III), except for the absence of the acetylated amino group on ring *B*. Therefore, it seemed possible to decide, using this compound, whether the amino group of colchicine was necessary for the molecule to exert its specific action on the mitotic spindle.



I, $R = -H$
II, $R = -NH_2$
III, $R = -NH-CO-CH_3$

In order to compare the inhibitory activities of colchicine and its desacetylamino derivative on cell reproduction, I used *in vitro* cultures of a transplantable murine mast cell tumour (cell line P–815–X_2)[5,6]. The culture techniques used and the medium have been described previously[7]. Additional components of the medium were: L-asparagine (0·1 mM), L-serine (0·1 mM) and *tris*-buffer (3 ml. of 2 per cent *tris*-(hydroxymethyl)-amino-methane in 0·15 N hydrochloric acid per 100 ml. of medium). Furthermore, leukovorin was replaced by folic acid (10 mg/l.). Approximately 200,000 cells were incubated in 2 ml. of this medium, which contained various concentrations of the inhibitor to be tested. After 24 h, cell reproduction was measured by hæmocytometer counts. The results obtained in a typical experiment are illustrated in Fig. 1. It can be seen that the inhibitory activity of desacetylamino-colchicine was approximately 10 times as high as that of the natural alkaloid, colchicine. In similar experiments the activity of desacetyl-colchicine (II) was found to be lower by a factor of 3 than that of colchicine. This is in good agreement with earlier reports[1]. It was concluded, therefore, that it is not the lack of the acetyl-group but rather the lack of the amino-group which is responsible for the increased activity of desacetylamino-colchicine, as compared with colchicine.

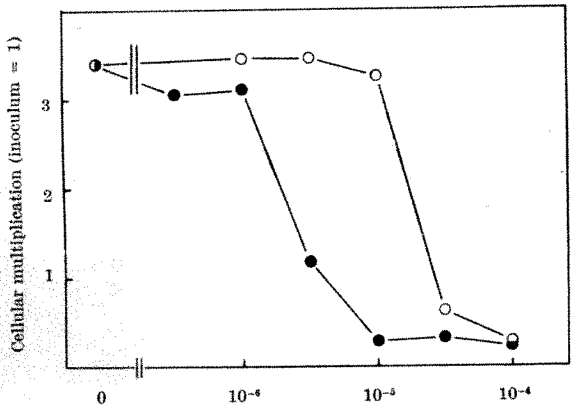


Fig. 1. Inhibition of cell reproduction by colchicine and desacetylamino-colchicine. ○, Colchicine; ●, desacetylamino-colchicine

The specific action of the inhibitors on the mitotic spindle was analysed by measuring the fraction of cells in metaphase, and in anaphase-telophase, respectively, 12 and 24 h after the addition of the inhibitor. The cells were fixed by mixing an aliquot of the cell suspension with an equal volume of ethanol–acetic acid–water 5 : 2 : 3. Afterwards the cells were centrifuged and resuspended in a small volume of 0·025 per cent crystal violet in 1 per cent acetic acid. In this suspension the cells in metaphase and those in anaphase-telophase were determined by hæmocytometer counts. Colchicine caused a pronounced accumulation of cells in metaphase, while at the same time the number of cells in anaphase-telophase fell below the control-level. The results summarized in Table 1 indicate that the metaphase block produced by desacetylamino-colchicine was of the same degree as that observed with colchicine. Similar results were obtained 24 h after the addition of the inhibitors.

Table 1. METAPHASE BLOCK OBSERVED AFTER 12-H EXPOSURE OF CELL CULTURES TO COLCHICINE AND DESACETYLAMINO-COLCHICINE

	Metaphases Percentage of total cells	Anaphases + telophases Percentage of total cells
Control (no inhibitor)	1·36	1·15
Colchicine 3×10^{-5} μmoles/ml.	23·5	0·53
Desacetylamino-colchicine 3×10^{-6} μmoles/ml.	30·6	0·36

Gustatory Thresholds in Patients with Hypertension

THERE is generally acknowledged to be a relationship of some sort between intake of salt and hypertension[1,2]. Dahl[3] has shown that groups habitually consuming large amounts of dietary salt show a greater incidence of hypertension than groups consuming lesser amounts. He has suggested that 'prehypertensives' eat more salt prior to the onset of their hypertension than do normotensive patients. Because of the possible importance of altered gustatory sensation, we decided to measure taste thresholds in hypertensives.

A method was used similar to one described by Richter and MacLean[4]. The subject was presented with a number of rows of cups with 4 cups in each row. Three of the 4 cups contained distilled water while the fourth contained either a salt or a sugar solution; the location of the fourth cup was at random.

The salt (or sugar) cups in successive rows went from most dilute to most concentrated. Salt solutions used for testing ranged from 0·00125 per cent to 0·64 per cent sodium chloride, doubling in concentration at each dilution so that there were 10 dilutions in all. Dextrose was used for testing threshold for sweetness; concentrations ranged from 0·1 per cent to 6·4 per cent, also increasing each time by a factor of two, giving seven dilutions for tasting. Solutions were mixed as per cent by weight/volume. For example, to prepare a 6·4 per cent solution of dextrose, 64 g of dextrose were dissolved in distilled water and then diluted until the total volume equalled 1,000 c.c. This method of preparation, although it has some theoretical disadvantages[5], seemed perfectly satisfactory for the purposes of our study.

The subject was asked to taste the fluid in each cup, spit it out, rinse his mouth with distilled water and proceed to the next cup. He was allowed to taste each cup more than once if he wished. When he completed all 4 cups in one row, the subject was asked to indicate which one contained the salt or sugar. If the selection was difficult, he was forced to guess. Comments made by the subjects were recorded (for example, 'different', 'quinine water', 'Epsom salts', etc.). After completion of one set of cups, the subject was asked to repeat the entire procedure. Two thresholds were determined: the lowest concentration at which a subject could correctly detect a difference on both tests, and the point at which the subject correctly recognized and could name the substance in solution as salt or sugar on both tests. No errors in selection of a cup at higher concentrations than threshold were apparent when these criteria were utilized. On the basis of previous work by Pfaffmann *et al.* and preliminary work of our own, it did not appear that fatigue or adaptation was likely to occur with repeated tasting[6].

The first group of ten hypertensive patients was drawn from the outpatient hypertension clinics. Three were females, seven males; three were white and seven Negro; their ages ranged from 28 to 57 years. The second group of ten hypertensive patients was selected at the State Penitentiary and all were male. Two were white, eight Negro; their ages ranged from 38 to 63 years. Hypertension was diagnosed when diastolic pressures were regularly over 100 mm Hg; no subject was on restricted salt intake or drug treatment. Each of the total of 20 patients had a control of the same sex and race, and age within two years. These controls were drawn from the hospital environment for the hospital group, and from the penitentiary for the prisoner group. Race was thought to be particularly important in view of published reports of differences in tasting ability between white and Negro groups in the United States[7,8]. Age has also been thought to be important[9].

Each subject was tested 1½ h after the last meal and was asked not to smoke for a like period, although there is evidence to indicate that smoking does not affect taste thresholds[10]. The first group of hypertensives and their controls were told that they were to be tested for ability to taste salt or sugar. The second group of hypertensives and their controls were asked to taste the solutions and to make their own identification, but this group was tested only for salt.

The results were analysed by two-tailed t-tests for matched data, based on the logarithms of the dilutions rather than on the raw data, because of the logarithmic progression of dilutions utilized. Comparisons were made for salt both on thresholds for 'difference' and on thresholds for actual identification of specific taste; for sugar these two thresholds coincided. If the first (or 'difference') threshold for salt were used, no difference could be noted between hypertensives and controls ($t = 1{\cdot}03$ for the first group, 0·90 for the second). Hypertensives did show, however, a highly significant diminution (see Table 1) in their ability to taste 'saltiness' as compared with their controls ($t = 3{\cdot}07$, $P < 0{\cdot}02$ for first group; $t = 3{\cdot}75$, $P < 0{\cdot}01$ for the second). There was no difference in threshold for sugar between hypertensives and their controls ($t = 0{\cdot}03$).

Table 1. 'SALTINESS' THRESHOLDS OF HYPERTENSIVES AND CONTROLS (mg %)

Hospital group		Penitentiary group	
Hypertensives	Controls	Hypertensives	Controls
0·04	0·01	0·16	0·16
0·04	0·16	0·16	0·08
0·08	0·02	0·32	0·08
0·02	0·01	0·04	0·04
0·16	0·04	0·32	0·04
0·16	0·02	0·02	0·02
0·16	0·04	0·08	0·02
0·08	0·08	0·16	0·16
0·04	0·01	0·16	0·04
0·32	0·02	0·32	0·08

Our data suggest that hypertensives may eat more salt because they cannot taste it as well as can normotensive individuals. Obvious next moves are to see if the abnormality described in this paper exists in siblings, offspring and parents of hypertensives, and to follow normotensive individuals whose taste pattern suggests that which we have noted in hypertensives. Such non-hypertensive groups would have advantages over the subjects reported in this communication in that there would be fewer complications by reason of such factors as natriuresis secondary to vascular damage, or dietary alterations imposed by medical advice or by the reading of lay literature on hypertension. Confirmatory data in such subjects would greatly strengthen the hypothesis that salt intake is an ætiological factor in hypertension rather than merely a reflexion of the disease or its treatment.

HÆMATOLOGY

Double Exponential Nature in Chromium-51 Red Blood Cell Survival Curves in Hæmoglobin E Thalassæmia and Relation with Reticulocytes

SEVERAL cases of hæmoglobin E thalassæmia were investigated for the survival of erythrocytes using auto red blood cells labelled *in vitro* with chromium-51. A standard method such as that described by Mollison[1] was adopted for the present investigation with the necessary precautions. Blood samples were collected at 10 min after the injection and afterwards on 1, 2, 3 and 5 days and thereafter every third day for a few weeks. Five ml. of blood sample was measured out, the plasma removed, hæmolysed with water to the original volume, and counted in a well-type scintillation counter at the completion of the test for each subject. The specific activity was plotted semi-logarithmically against time without any correction for chromium-51 elution. A pronounced bending in the curves was observed between 2–4 days, particularly in cases of patients. Normally, erythrocyte survival curves with chromium-51 could be fitted with an exponential type of decrease at least for the first few weeks with a little depression at the beginning due to a rapid elimination at the earliest stage[2]. Eadie[3] has, however, discussed the precise nature of the survival curves.

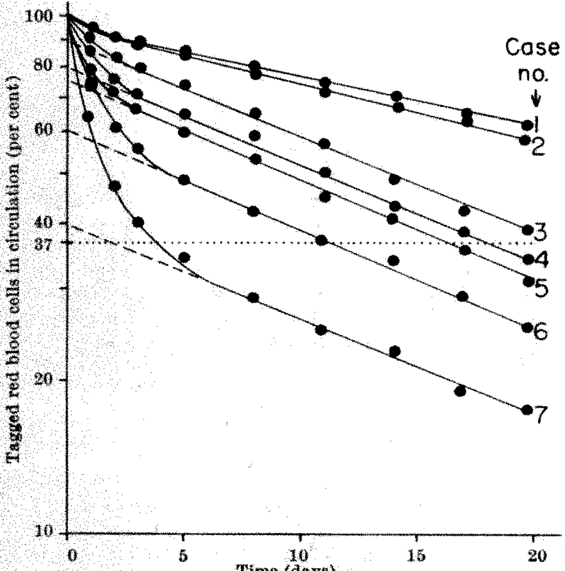

Fig. 1. Level of red blood cells labelled with chromium-51 in blood with time

Fig. 1 shows the survival curves of the red blood cells labelled with chromium-51 of the two normal subjects and five hæmoglobin E thalassæmia patients. The present curves for the patients show clearly the presence of double exponential nature consisting of a fast and a slow component. The gross mean life can be obtained directly from the curves as the time required to fall to 37 per cent survival, which ranges from 4 to 21 days for the five patients. These curves can, however, be analysed using an equation:

$$Rt = A e^{-r_a t} + B e^{-r_b t}$$

where Rt denotes the fraction of the tagged red cells in circulation at any time t, A and B represent the percentages of the so-called fast and the slow fractions, and r_a and r_b stand for their respective rate constants.

Table 1. ANALYSIS OF CHROMIUM-51 RED BLOOD CELL SURVIVAL CURVES AND RELATION WITH RETICULOCYTES OF HÆMOGLOBIN E THALASSÆMIA CASES

Case No.	Rectic. (per cent)	T_g (days)	A (fast) (per cent)	B (slow) (per cent)	T_a (days)	T_b (days)
1 N	0·3	44	5	95	0·6	48
2 N	0·3	38	5	95	0·6	42
3 Th	4	21	10	90	0·7	24
4 Th	6	18	20	80	0·9	22
5 Th	7	16·5	25	75	0·9	24
6 Th	12	11	40	60	1·0	23
7 Th	28	4	60	40	1·0	24

The actual analysis of the curves shows the 'fast component' to be a rapidly eliminating fraction having a mean life of about a day, whereas the 'slow component' gives a mean life of 22–24 days (half-life about 16 days) for the patients. It is striking to note that the mean life of this second component for all the five patients is fairly constant, which is about half of that of normal subjects. It is obvious that the variable factors are the fractional quantities A and B, which are responsible for showing a variation in the gross mean life as obtained by chromium-51. Table 1 summarizes the results.

Fig. 2 shows a linear relationship of the gross mean life with the contribution of the components—an

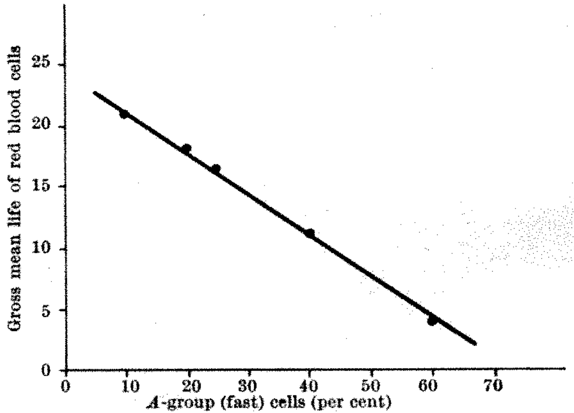

Fig. 2. Relation of the gross mean life of red blood cells of the patients with their 'fast fraction'

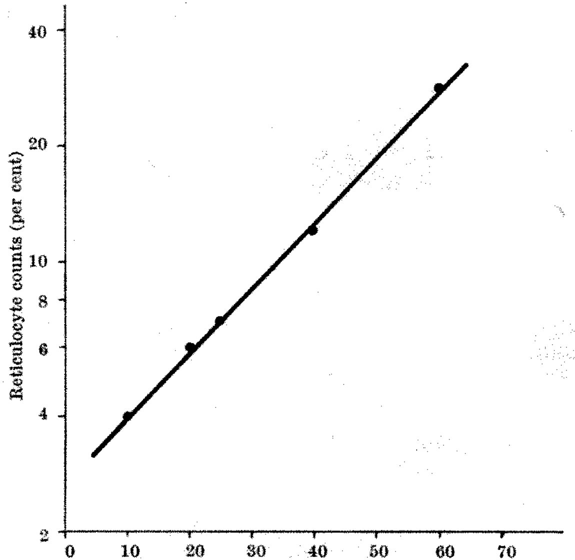

Fig. 3. Relation of the reticulocyte counts of the patients with their 'fast fraction'

inverse relation with the fast group. Attempts were made to correlate any of these fractions with any of the clinical parameters such as index of anæmia, plasma hæmoglobin, fœtal hæmoglobin, plasma bilirubin and reticulocytes. Only the reticulocytes percentage at the beginning of the test could show a relation with the quantities of these fractional components. Fig. 3 shows a semi-logarithmic relation of the reticulocyte percentage with the fast component.

The investigation leads to the conclusion that in all hæmoglobin E thalassæmia patients at least a fraction of the red cell population has fairly constant life span, though short compared with normal, which is independent of any index of anæmia. A rapidly eliminating fraction of the cell population is related to reticulocytes and probably to the very young cells, but there is no indication that they hæmolyse at the very early stage. It can, however, be said that this fraction may be rapidly eluting chromium-51 in the circulation, or alternatively, they may be actually dying out very rapidly due to trauma or other interference caused by the process of labelling which might indicate that they are very fragile in nature.

HISTOLOGY

Submicroscopic Structure of the Peritrophic Membrane in Arthropods

A PERITROPHIC membrane, in the form of loosely connected concentric layers of substance wrapping the ingesta, has long been described in the mid-gut of different classes of arthropods (insects, myriapods, crustacea and onychophora).

Investigations with the electron microscope on the structure of this membrane have been so far reported only on insects[1-9].

The single layers, obtained by delamination of the concentric layers by mechanical procedures, consist essentially of fibrillar networks. The size and disposition of the fibrils in the networks vary in the different insects. In some species, a thin amorphous film is stretched across the holes of the network[2]. Unorganized fibrils, scattered at random in an amorphous ground substance, are associated with the networks in some insects[5] or are the only components detected in others[2,4,9].

In the work reported here, observations on the peritrophic membrane with the electron microscope have been extended to species belonging to other groups of arthropods : *Glomeris* sp., *Iulus albipes* Koch (Myriapoda), *Eriocheir sinensis* Milne-Edwards (Crustacea Decapoda), *Xiphosura* (= *Limulus*) *polyphemus* L. (Xiphosura).

In this material, the peritrophic membranes were collected by dissection of the midgut, washed and disintegrated in distilled water by shaking or by ultrasonic waves (Siemens, sonic emulsifier).

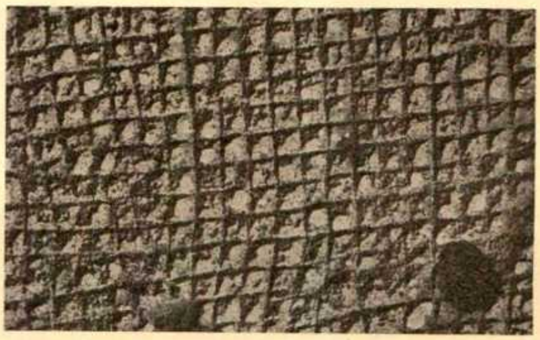

Fig. 1. Peritrophic membrane of *Iulus albipes* (× 23,500). (*Photo: Grégoire; R.C.A.*)

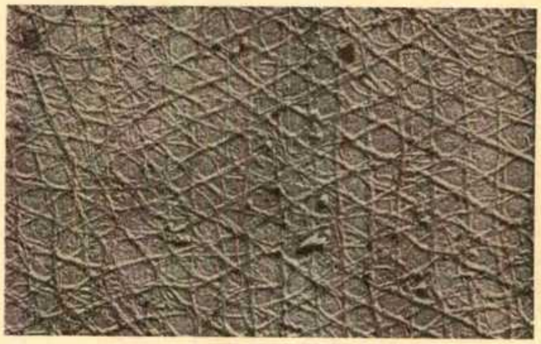

Fig. 2. Peritrophic membrane of *Eriocheir sinensis* (× 32,000)

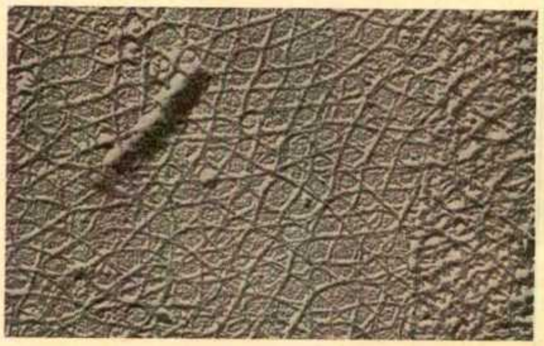

Fig. 3. Peritrophic membrane of *Xiphosura polyphemus* (× 34,400). (*Photo: Grégoire; R.C.A.*)

Drops of aqueous suspensions of these dissociated membranes were deposited on to 'Formvar' coated screens, drained, dried, shadow-cast with palladium, and examined with the electron microscope (R.C.A. Emu-2 or Siemens Elmiskop 1).

As in several insects[5], the peritrophic membranes of these arthropods consist of fibrillar networks. Because of the extreme flexibility of the single layers, easily shrunk, stretched or folded during desiccation on the 'Formvar' films, the patterns of the networks may assume various appearances in the different portions of the preparations. However, in *Iulus albipes*, two systems of parallel fibrillar strands, disposed at right angles or obliquely and delimiting rectangular or lozenge-shaped holes (Fig. 1), were observed in most preparations. In *Eriocheir sinensis* (Fig. 2) three systems of strands enclosed hexagonal holes. A similar structure, though less regularly disposed, was recorded in the peritrophic membrane of *Xiphosura polyphemus* (Fig. 3). Fibrils were especially visible in the strands of the membrane of *Eriocheir sinensis* (Fig. 2). The presence of a typical peritrophic membrane in *Xiphosura* is of particular interest, owing to the fact that this structure has not been described in Chelicerates, with the exception of the old observation of Tulk[10] in *Phalangium opilio*.

These observations suggest that fibrillar networks characterize the submicroscopic structure of the peritrophic membrane not only in insects but also in the other classes of arthropods.

Intracellular Calcification in a Coccolithophorid

Hymenomonas sp., a euryhaline coccolithophorid chrysomonad, was raised axenically in a chemically defined medium[1] containing lactic acid, modified by raising the concentration of magnesium and calcium to 10^{-2} M, of phosphate to 10^{-3} M and adding carbonate 10^{-6} M and 10 mg per cent ethylenediamine tetraacetic acid. Coccolith formation was discernible macroscopically when these organisms were cultured in constant fluorescent light for 2 weeks at 18°–20° C. Phase-contrast microscopy of the growing cultures showed abundant coccoliths extracellularly and on the surface of the chrysomonad. The appearance of some individual protozoa suggested that coccoliths might be located intracellularly. This observation is supported strongly by the following findings.

Actively growing cultures were centrifuged at 1,200 *g* for 15 min at 4° C. The precipitate, fixed in 10 per cent (v/v) neutral formalin in 95 per cent (v/v) ethanol, was embedded in paraffin and cut serially at 4μ; undecalcified sections were examined with the following histological and histochemical procedures[2]: von Kossa, hæmatoxylin-eosin, periodic acid-Schiff, methylene blue extinction and toluidine blue stains. Bright-field, phase, dark-field and polarization microscopy were utilized on stained and unstained sections.

These investigations revealed intracellular, von Kossa-positive, ovoid bodies which were periodic acid-Schiff-positive, metachromatic and strongly basophilic at *p*H 2·62. The average cell had about 5 of these anisotropic bodies, the variable diameters of which ranged from approximately 1/10 to 1/20 of the cell diameter. Decalcification of the sections with either 0·1 N ethylenediamine tetraacetic acid or 0·1 N hydrochloric acid while under microscopic observation resulted in still discernible intracellular bodies which had become isotropic and had lost the ability to stain with silver nitrate, while all other reactions remained unchanged. The same results were obtained with extracellular coccoliths.

These data are consistent with the hypothesis that in *Hymenomonas*, a representative of the most primitive protozoa, coccolithogenesis is an intracellular, biphasic process, adhering to the general pattern of biological calcifications. It is suggested that the primary formation of the organic matrix of the coccolith is followed by a secondary calcification. The mature coccoliths are then extruded into the surrounding medium. X-ray diffraction powder investigations and chemical analyses of the extracellular coccoliths lend further support to the present histological observations[3].

These observations confirm and extend the reports by Parke and Adams[4], and Paasche[5]. The chemical nature of the matrix, the metabolic processes involved in this primitive calcification and the role of photosynthesis in this process are at present under investigation.

PATHOLOGY

Effect of Cholesterol Oleate on the Phagocytic Function of the Reticulo-Endothelial System

THE cells of the reticulo-endothelial system in contact with the blood stream are found mainly in the liver and spleen. One of their more important functions is phagocytosis of particulate matter such as bacteria, virus, colloidal dyes or finely divided carbon. It seemed reasonable to assume that the function of these cells may be modified by the nature of ingested material. This hypothesis has been explored by injecting intravenously different suspensions of fatty acid esters of known chemical constitution and afterwards measuring the reticulo-endothelial system activity by the carbon clearance test. Thus it has been shown that glyceryl trioleate stimulates the reticulo-endothelial system function whereas ethyl oleate has a depressant action[1]. This suggested that the alcohol with which the fatty acid was combined might be of importance in determining the biological actions of the ester. These findings have been confirmed and extended[2,3] using various esters derived either from glycerol or ethyl alcohol. Accordingly, it seemed of interest to study the effects of a cholesterol ester and compare its action with the substances previously mentioned.

A 10 per cent suspension of cholesterol oleate (B.D.H.) was made by homogenizing the melted lipid in 5 per cent dextrose water containing 1 per cent 'Tween 20'. The particle size was very variable and many measured between 5 and 15μ. This was injected intravenously into male mice weighing 15–25 g. The granulopectic activity of the reticulo-endothelial system[4] was measured after intravenous injection of colloidal carbon in a dose of 8 mg/100 g. The phagocytic index K measures the rate of clearance of carbon from the blood and the corrected phagocytic index α is derived from the equation $\alpha = \sqrt[3]{K} \times \frac{W}{wls}$ where W = body-weight and wls = weight of liver and spleen. Following doses of 10 and 30 mg of cholesterol oleate the granulopectic activity was measured in groups of eight mice at intervals of 1, 2, 3, 4, 5, and 7 days. The control group is composed of eighteen normal mice. Table 1 records the average of results obtained in this experiment.

Table 1. EFFECT OF 10 AND 30 MG DOSES OF CHOLESTEROL ESTER ON THE PHAGOCYTIC COEFFICIENT K AND a

Dose	Indices	Time in days after injection					
		1	2	3	4	5	7
10 mg	K a	0·018 3·0	0·029 4·1	0·035 4·5	0·044 4·2	0·080 4·5	0·049 4·1
30 mg	K a	0·010 2·1	0·010 1·8	0·016 1·6	0·024 2·5	— —	0·055 3·2
Control	K a	0·044 4·4					

It was noted that the largest dose which could be given without mortality (mainly in the larger mice) was 50 mg. The spleens of all animals in this large dosage group were abnormal on examination by naked eye 24 h later. They were granular, tomato pink and slightly enlarged. Paraffin sections for microscopy were prepared from both livers and spleens. The histology of the spleen is shown in Fig. 1. It appears that cholesterol oleate in a dose of 30 mg causes a severe inhibition of phagocytic function for two or three days. This degree of blockade compares favourably with that obtained by injection of inert colloids such as saccharated iron oxide and unlike the latter is not followed by a phase of hyperactivity. The advantages in the use of this material are, first, the particles are not agglutinated by serum and the risk of embolism is reduced; secondly, the particle size can be controlled by conventional methods of preparation; and thirdly, it is almost certainly metabolized and excreted. Following the larger dose of 50 mg the lymphoid follicles of the spleen remain intact but are surrounded by a fatty red pulp of poor phagocytic capacity. This histological change suggests that cholesterol esters may be useful for investigating the interdependence of phagocytic and lymphoid tissue in immunological reactions. Unfortunately this 50 mg dosage causes focal necrosis in the liver although perhaps this could be circumvented by the use of a more uniform preparation of smaller particle size.

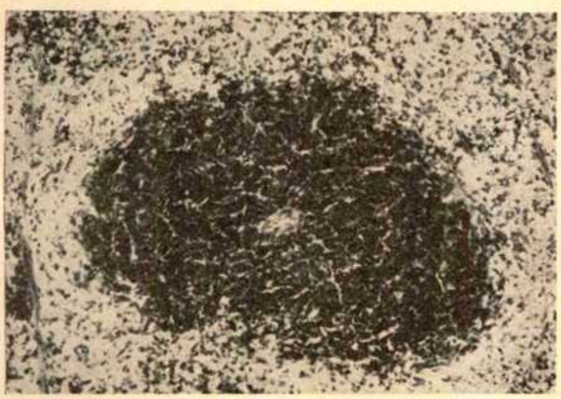

Fig. 1. Spleen after 50 mg cholesterol oleate showing intact Malpighian body surrounded by hypocellular fatty pulp. (Hæmatoxylin and eosin, × 90)

The 10 mg dose produces no striking changes in reticulo-endothelial system function, a finding which contrasts markedly with the stimulating effects of the glycerol esters, triolein and tricaprin. Although the reasons for these differences are not known, the finding lends further support to the view that the reticulo-endothelial system activity can be modified by administration of lipids the chemical nature of which is important in determining the effect produced.

Anaphylaxis in Mice with Fragments of Rabbit Antibody

AT present there is much interest in the relationship between the sensitizing capacity of antibodies and their affinity for tissues. Ovary and Karush[1] found that univalent fractions I and II (*F* I, *F* II) obtained from purified rabbit anti-haptene antibody by papain digestion were unable to sensitize the guinea pig for direct passive cutaneous anaphylaxis (PCA) or reversed PCA. They postulated that the site necessary for the fixation of antibody to guinea pig tissues was not present on fractions I and II but was carried by fraction III. Reversed PCA could be produced with *F* III and horse anti-rabbit globulin. Ishizaka *et al.*[2] stated that pepsin-digested rabbit globulin, which presumably lacks fraction III, would not induce inflammatory reactions in guinea pig skin and would not fix complement. Taranta and Franklin[3] also found that pepsin-digested antibody did not fix guinea pig complement *in vitro*. It seemed of interest to us to test papain and pepsin digesteo fragments of rabbit γ-globulin in a system in which tissue fixation of antibody does not seem to play a part, namely, anaphylaxis in the mouse. In this species maximal incidence of anaphylaxis with rabbit antibody can be obtained by injecting antibody and antigen intravenously in rapid succession[4].

Swiss-Webster female mice weighing 17–25 g were inoculated intraperitoneally with 5 billion *B. pertussis* organisms to increase their susceptibility to passive anaphylaxis[5]. Five days later the animals were injected intravenously with antibody and antigen in rapid succession. Rabbit γ-globulin was degraded with papain by the method of Porter[6] and with pepsin by the method of Nisonoff *et al.*[7]. Digestion of rabbit γ-globulin with papain results in the production of

Table 1. PASSIVE ANAPHYLAXIS WITH RGG*, *F* I† AND *F* II† AS ANTIBODY

Pertussis-sensitized mice injected intravenously‡ with:	Deaths/Total
2 mg *F* I§ + 1 mg BSA	0/8¶

10 mg anti-BSA (pepsin) + 1 mg bovine gamma globulin (BGG)	0/5

* Antibody fragments from papain digested rabbit γ-globulin.

† 38 per cent antibody.

univalent antibody fragments (*F* I, *F* II). Digestion of rabbit γ-globulin with pepsin results in a decrease in sedimentation coefficient from $7S$ to $5S$ without destruction of its capacity to form specific precipitate, indicating that the $5S$ fragment is bivalent. Treatment of the $5S$ unit with a disulphide-splitting agent such as cysteine results in the formation of fragments with the properties of univalent antibody and $S = 3{\cdot}5$ (ref. 7).

The results in Table 1 demonstrate that 4 of 8 pertussis-inoculated mice succumbed to anaphylactic shock when injected intravenously with 2 mg of rabbit γ-globulin (anti-bovine serum albumin) containing 0·8 mg antibody, and 1 mg of bovine serum albumin. However, mice injected with bovine serum albumin and 2 mg (or even 10 mg) of *F* I or *F* II prepared from the aforementioned rabbit γ-globulin by digestion with papain showed no symptoms of anaphylaxis. The failure of *F* I or *F* II to produce anaphylaxis in mice cannot be explained by the inability of these fractions to combine with bovine serum albumin since *F* I was found to inhibit the hæmagglutination of bovine serum albumin coated red cells by antibovine serum albumin serum.

The results in Table 2 demonstrate that pepsin digested rabbit anti-mouse globulin killed 9 of 13 pertussis-inoculated mice, and pepsin digested rabbit anti-bovine serum albumin killed 2 of 8 animals. Addition of cysteine to pepsin degraded antibody destroyed its lethal effect, as well as its ability to precipitate with homologous antigen. It should be noted that pepsin digested rabbit antibody was only about 1/10 as active on a weight basis as undegraded rabbit antibody. However, it is unlikely that the biological activity of pepsin digested rabbit γ-globulin is due to the presence of small amounts of undegraded γ-globulin in the preparation. If such were the case, cysteine treated pepsinized antibody should kill mice since we have found that the activity of undegraded γ-globulin in mice is unaffected by 0·01 M cysteine. As shown in Table 2, pepsin digested rabbit γ-globulin treated with cysteine had no lethal effects.

The property of antibody which seems to be essential for the induction of anaphylaxis in the mouse is the capacity to form aggregates. Pepsin degraded bivalent antibody produced anaphylaxis in mice, but pepsin digested antibody reduced to univalent fragments by treatment with cysteine was inactive (Table 2), as were univalent papain digested fragments (Table 1). It is possible that anaphylaxis in the mouse is initiated by antigen-antibody aggregates in the circulation which trigger an anaphylotoxin-like mechanism.

It should be noted that the ability of pepsin digested rabbit antibody to kill mice is not likely due to tissue-fixing properties of the antigen with which it combines. Pepsin digested anti-bovine serum albumin plus bovine serum albumin was lethal to mice, but it is unlikely that bovine serum albumin fixes to mouse tissue, since it has recently been demonstrated that bovine serum albumin will not produce reversed passive cutaneous anaphylaxis in mouse skin[8].

Intracellular Lymphocytes in Leukæmia

IT has recently been reported that lymphocytes may exist inside large cells cultured from leukæmic human bone marrow during the phase of remission[1].

This phenomenon occurred exceptionally also in our material. Bone marrow was grown in Sykes–Moore chambers from a man with chronic lymphatic leukæmia and Coombs's positive hæmolytic anæmia. Large elongated cells developed rapidly. These cells appeared to be surrounded and attacked by lymphoid cells growing in the same bone marrow specimen (Fig. 1). The affair usually ended with the death and disintegration of the large cells.

Bioassays in new-born or young Swiss mice yielded negative results within a relatively short period of observation (5–12 months): 1·6 per cent of 488 mice inoculated with fluids from this and other leukæmic human bone marrow tissue cultures, or with leukæmic human brain extracts, developed generalized lymphatic leukæmia, as compared with 1 per cent incidence of leukæmia in 384 control mice inoculated with non-malignant human bone marrow tissue culture fluids or brain extracts. This is in good correlation with results obtained in other studies[2,3]. (*Note added in proof*. These human leukæmic brain extracts were claimed to have caused a high incidence of ascitic mesenteric lymphosarcomas in adult Swiss mice within 2–5 weeks (Schwartz, S. O., Gordon Research Conferences, Cancer, 1961).)

As to the mechanism of the intracellular existence of lymphocytes in leukæmia, the following considerations are suggested: (1) Histiocytes engulf leukæmic lymphocytes in order to destroy them. (2) The large cells may serve as a feeder layer for the lymphocytes.

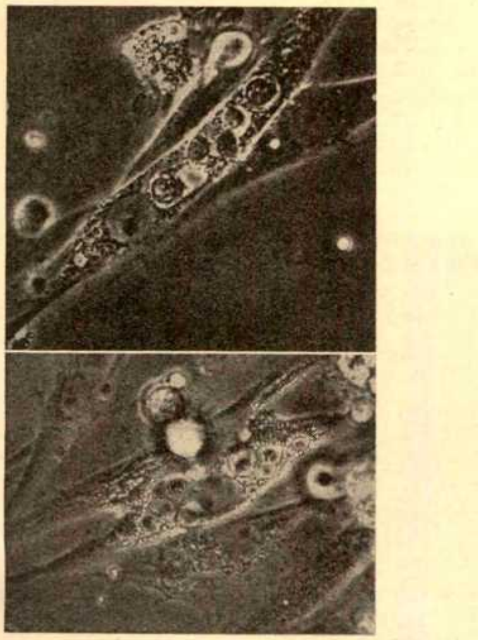

Fig. 1. Two large elongated cells grown from a leukæmic human bone marrow are invaded by lymphoid cells of the same bone marrow tissue culture. (Phase contrast)

(3) Lymphoid cells of auto- or homo-logous immune activity attack host cells. Autoimmune phenomena are frequent in human lymphatic leukæmia[4,5], and occur in mouse leukæmia[6]. Emergence of immunologically hostile lymphoid cell clones may be stimulated by a leukæmogenic virus in mice[7]. Lymphocytes are known to be capable of attacking Rous sarcoma cells[8] and homologous mouse cells[9], leaving disintegrating carcasses of such cells behind.

ANATOMY

Ion Etching of Dental Tissues in a Scanning Electron Microscope

TOOTH sections have been bombarded with a 5-kV argon ion beam inside the specimen chamber of a scanning electron microscope. This apparatus was designed so that the ion beam could be focused into a 1·5-mm diameter spot on the surface of the specimen, covering the area viewed by the microscope. The ions were extracted from a radio-frequency ion source and were focused by two electrostatic lenses on to the specimen, through two apertures. The pressure in the specimen chamber when the ion source was running was better than 10^{-6} mm mercury. The ion beam density was not uniform over its cross-section, but varied from about 10 m. amp/cm^2 at the centre to zero at the edge; this enabled us to check that, for the current densities we utilized, the nature of the changes in the specimen surface that was produced was not a function of the rate of etching. The bombarded area was kept to a minimum to reduce the amount of material deposited on the electron collection system, and reduce the temperature rise, which we have calculated to be less than 100° C, using the values of thermal conductivity given by Craig and Peyton[1]. The total ion current was kept to about 15μ amp. The micrographs were taken with a 16-kV scanning electron beam and only the high-energy reflected electrons were used to form the picture. This allowed micrographs to be taken with a resolution better than 500 Å., even though the specimen tended to charge under the electron beam. This method of observation also allows pictures to be taken while the surface is under bombardment; but for this work it was found preferable alternately to bombard for, say, 5 min, and then observe the surface at leisure. The ion beam made an angle of about 40° to the specimen normal: the direction is indicated by the arrow on the micrographs. The surface was also viewed at an oblique angle, as is indicated by the magnification symbols on the micrographs (Figs. 1 and 2).

The specimens, which were sections of teeth (human, rodent (*Myocaster coypu*) and marsupial (*Macropus*)), were polished down to a thickness of about 100μ before mounting. They were further polished on metallurgical polishing papers (down to a grade 4/0, John Oakey and Sons, Wellington Mills, London, England), after sticking them with 'Araldite' adhesive to an aluminium backing plate. Before bombardment, the specimens were covered with a 300 Å. layer of aluminium to keep the electrical resistance from the specimen to earth as low as possible; this thickness of aluminium would be removed by the ion beam in less than 10 sec.

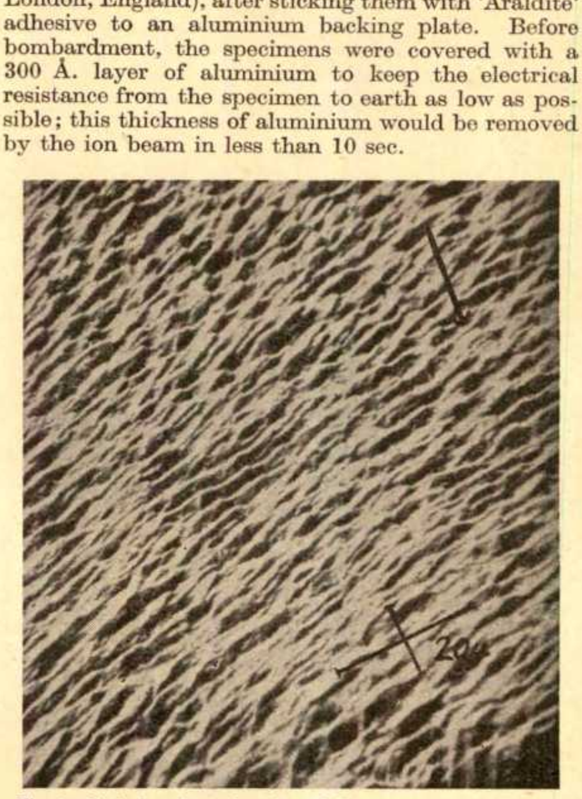

Fig. 1. Etched surface of section of *Macropus* enamel, showing enamel rods running nearly parallel to the surface

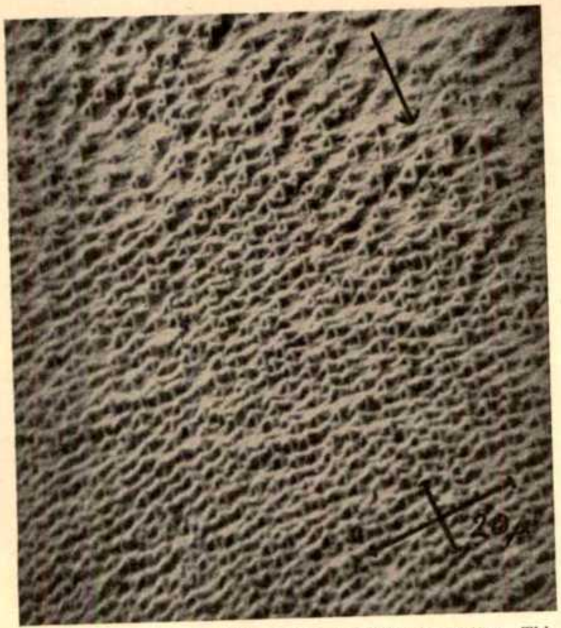

Fig. 2. Etched surface of the section of *Macropus* dentine. This region is close to the pulp chamber, hence the dentinal tubules are close together. The peritubular dentine can be seen 'standing proud' of the intertubular dentine

After observation in the scanning microscope the specimens were also examined by optical methods and by taking replicas, which were studied in a Siemens electron microscope. The surface was found to be hard, and true replicas could be produced without pulling crystallite away from the surface.

For a given ion beam, the rate of etching depends on the chemical composition of the specimen at the surface and on the angles that the ion beam and the crystal lattice make with the specimen surface.

In a region of constant composition, the production of a surface topography due to differential etching-rates can only depend on differences in the orientation of crystalline structural units that have been etched away. Enamel has a fairly uniform composition, but it was etched differentially to produce a surface profile in which the rod structure of the tissue could be visualized (Fig. 1). We suggest, therefore, that the differences in sputtering-rate which we have observed in enamel are related to the differences known to exist in the orientation of the crystallites of hydroxyapatite[2], and that ion beam etching may have a potential as a method for revealing these differences. Dentine was etched away more rapidly than enamel: enamel is known to be the more highly mineralized. Intertubular dentine was eroded more rapidly than peritubular dentine (Fig. 2): the latter is again known to be the more highly mineralized. We suggest that these differences in sputtering-rates are primarily related to these differences in mineralization.

The scanning electron microscope proved of great value in enabling the etching to be followed, until a convenient amount of material had been removed. As the specimen was bombarded in its correct position for viewing by the scanning electron microscope, previously observed areas could be rapidly re-located after each period of bombardment.

Although Figs. 1 and 2 are scanning electron micrographs, replicas were taken of the specimen surface after it had been removed from the scanning microscope, and these were examined in a transmission electron microscope (Siemens Elmiskop I).

Good replicas were obtained, and there was no sign of any material having been pulled away from the surface with the replica, which is a common fault when replicas are taken of surfaces that have been etched with chemical solutions.

We thank Prof. C. W. Oatley for his encouragement and the facilities provided, and the Atomic Energy Research Establishment, Harwell, for financial support. Some of the material was purchased out of a grant from the Advisory Medical Research Committee Fund of the London Hospital and Medical College. We would also like to thank Major J. J. Buxton for his continued help.

RADIOBIOLOGY

Treatment for Removal of Inhaled Radioactive Ceria ($^{144}CeO_2$) from the Lungs of Rats

INHALATION is one of the most probable routes for entry of radioactive elements into the body. Relatively insoluble, radioactive particles deposited in the lung are normally retained for long periods of time resulting in high, local radiation dosages which may lead to pulmonary damage, for example, fibrosis and carcinoma[1]. Therefore, it is important that methods are available for increasing the rate of clearance of radioactive particles from the lung and from the body. This communication reports preliminary results of tests to remove inhaled ceria ($^{144}CeO_2$) (in equilibrium with its daughter product, praseodymium-144). Cerium-144 is a fission product occurring mainly in insoluble form and accounts for much of the radioactivity remaining 1–4 years after nuclear fission[2]. Cerium-144, with a 290-day half-life, decays by β-γ emission to praseodymium-144, which has a 17-min. half-life.

The techniques used for exposing ten-week-old Sprague–Dawley strain rats to radioactive aerosol were essentially those described by Willard[3]. The rats were exposed for about 15 min. to an aerosol generated from a 0·3 per cent suspension of $^{144}CeO_2$. At the end of the exposure to radioactive aerosols the rats were divided into various groups and sub-groups for subsequent treatment. The number of animals used and the treatment to which they were exposed are given in Table 1. The test materials were administered as aerosols for a period of 30 min., in the same exposure chamber used for administering the radioactive material. A group of rats was treated immediately after exposure, then twice a day for the following three days, and once a day for the next three days, and thereafter every second day until the fifteenth day. Another group of rats was given the same treatment regimen, except for omission of the treatment immediately following exposure to $^{144}CeO_2$. Rats were killed in the first experiment by intraperitoneal injection of sodium pentobarbital one week after the last treatment (21 days post-exposure), and in the second experiment, on the day following the last treatment (15 days post-exposure). The lungs and liver were removed and prepared for counting by wet ashing[4]. Samples were counted with an end window proportional counter.

Table 1. EFFECT OF DIFFERENT AEROSOL TREATMENTS ON REMOVAL OF INHALED ^{144}Ce–^{144}Pr FROM RATS

Rats were treated by 30-min. exposures to aerosols produced from 1 per cent phenylephrine hydrochloride, 25 per cent DTPA, and 3 per cent 'Pluronics *F*68' solution. The animals were killed in the first experiment one week after the last treatment (21 days after exposure), and in the second experiment the day following the last treatment (15 days after exposure)

Experiment	Treatment regimen		^{144}Ce–^{144}Pr content of tissues*			
			Retained in lungs		Retained in liver

	DTPA		290 ± 58	31	14 ± 1·9	22

*The ^{144}Ce–^{144}Pr content of the carcasses, as well as that of the lungs and livers, was decreased by the therapy.

†Post-exposure.

‡Mean and 95 per cent confidence intervals around the mean.

DTPA (diethylenetriamine pentacetate) was the most effective agent for removing radioactive particles from the lungs. The lungs of the DTPA-treated animals contained 90 per cent less ^{144}Ce–^{144}Pr than control animals. ^{144}Ce–^{144}Pr was excreted without significant deposition in liver, in which it generally accumulates. DTPA exerted its effect not only when administered immediately after inhalation of radioactive particles, but also when treatments were started on the next day, although to a lesser degree. Experiments now in progress using whole-body counting techniques indicate that DTPA is also effective in removing ^{144}Ce–^{144}Pr from the lungs of dogs.

'Pluronics *F*68' (Wyandotte Chemical Co.), a non-ionic dispersing agent, was less effective than DTPA. Possibly the action of this dispersing agent was limited to the upper part of the respiratory tract; thus accounting for its lesser effectiveness. In a separate experiment the difference in concentration of DTPA and 'Pluronics *F*68' aerosols did not account for the greater effectiveness of DTPA in removing ^{144}Ce–^{144}Pr.

The results of the phenylephrine hydrochloride treatments were not conclusive.

These experiments show that the chelating agent, DTPA, very effectively removes relatively insoluble ^{144}CeO$_2$ particles from the lung. These encouraging results suggest that other insoluble radioactive particles may be similarly removed from the lung if appropriate chelating agents are found. In selecting the chelating agent consideration must be given to the possibility of translocating radioisotopes from the lung to more radiosensitive organs. In the present case, ^{144}Ce–^{144}Pr cleared from the lung was also removed from the body.

We thank the Geigy Pharmaceutical Co. for supplying the DTPA, and Mr. M. D. Snyder for making the aerosols and for his valuable help during the experiments. We also thank Mr. W. Skinner, Mrs. E. T. Edmerson and Mr. J. P. Herring for preparing and counting samples.

Balance of Potassium, Rubidium and Cæsium between Japanese People and Diet and Assessments of their Biological Half-Times

THE biological half-times of radionuclides of the alkali metals have been determined by several investigators by using laboratory animals and even man; excretion and retention analyses were used following a single dosage of radionuclide for the calculation. These methods, however, are subject to criticism because of the extrapolations of animal data to man and also the use of a single dose for a long-term administration; this is especially the case with cæsium-137, which has been incorporated in man through foodstuffs as a result of world-wide contamination from nuclear weapon testings.

The biological half-time of cæsium-137 is short and an equilibrium is attained between the human body and diet within a year. When equilibrium has been attained, the ratio of the levels of cæsium-137 in the human body and diet should be the same as that of non-irradiated cæsium. Thus it would be possible to presume the levels of cæsium-137 in man on the basis of diet-levels. This consideration inspired an examination of the distribution of common alkali metals in man and his diet.

Measurements were made of potassium, rubidium and cæsium in the human soft tissues, muscles and bones from autopsies collected in Tokyo during August 1959–August 1960. The complete data and discussions were published elsewhere[1]. The total-body amount of potassium and cæsium was estimated from the concentrations in muscle, bone and soft tissues, and the weight percentage composition of standard man, assuming the total-body consists of 43 per cent of muscle, 14 per cent of bone with bone marrow and the remainder of soft tissues. In the case of rubidium, the average ratio of rubidium/potassium in the analysed tissue samples ($2·7 \times 10^{-3}$) was multiplied by the total-body potassium for the estimation.

The concentrations of potassium and cæsium were respectively as follows: 2·39 mg and 29·5 mμg in muscle, 1·89 mg and 15·7 mμg in bone and 1·51 mg and 12·7 mμg in soft tissues (per gram of fresh tissues). The estimate for the standard man of 70 kg body-weight showed the total-body amount of potassium as being 136 g or 0·19 per cent by weight; these values are in good agreement with those based on body radioactivity measurements reported by other authors[2]. The concentration of rubidium and cæsium in the total-body was $5·1 \times 10^{-4}$ and $2·0 \times 10^{-6}$ per cent by weight respectively and the total amount in the standard man was 0·36 g and $1·4 \times 10^{-3}$ g, respectively. The estimate of the total-body cæsium recommended by the International Commission on Radiological Protection, namely, less than 10^{-5} g, seems astonishingly low in comparison with the present estimate. On the other hand, rubidium was found approximately one-third of the recommended value of 1·2 g.

Total diet samples were supplied by Dr. H. Hayami of the National Institute of Nutrition, Japan. The complete diet consumed by a member in a family was collected from ten families chosen at random from a number of sites in Japan. The category of family was divided into three: urban adult, rural adult and rural children. The composite sample of ten families was analysed for potassium, rubidium and cæsium. The results are shown in Table 1. The daily intake of the alkali elements by Japanese people would lie somewhere between the values for urban and rural, and an approximate estimation by a simple averaging resulted in 1·4 g of potassium, 1·5 mg of rubidium and 0·01 mg of cæsium as the daily intakes by an adult Japanese.

Reliable statistical data for the average body-weight of adult Japanese are not available, but 56 kg is believed as a justifiable value which is equivalent to 80 per cent in standard man. On this basis, the total-body amount for Japanese was computed as shown in Table 2.

Assuming a single exponential function in excretion and the complete absorption from the gastro-intestinal tract, the biological half-times (days) of potassium, rubidium and cæsium were calculated as 54, 140 and 76, respectively, as presented in Table 2.

Table 1. DAILY INTAKE OF POTASSIUM, RUBIDIUM AND CÆSIUM BY JAPANESE PEOPLE

Category	K (mg)	Rb (mg)	Cs (μg)
Urban adult	1,231 ± 244 (9)	1·26 ± 0·22 (7)	8·9 ± 2·6 (9)
Rural adult	1,638 ± 426 (9)	1·65 ± 0·33 (7)	11.0 ± 2·5 (9)
Rural children	1,014 ± 329 (6)	1·44 ± 0·87 (5)	8·6 ± 4·2 (6)

No. in parentheses represent number of composite (10 families each) samples of complete diet. The means and errors are based on assumed normal distribution.

Table 2. ESTIMATES OF BIOLOGICAL HALF-TIMES OF POTASSIU RUBIDIUM AND CÆSIUM ON THE BASIS OF DAILY INTAKE AND TOTA BODY AMOUNT (56 KG BODY-WEIGHT)

	K (g)	Rb (mg)	Cs (mg)
Total-body amount (Q)	110	300	1·1
Daily intake (q)	1·4	1·5	0·01
Q/q	79	200	110
Biological half-time (day) ($Q/q \times 0·693$)	54	140	76

These values are in agreement with the half-time (days) in total-body recommended by the International Commission on Radiological Protection namely, 58, 45 and 70, respectively, except fo rubidium. The reason for the higher value o rubidium is not clear.

C. R. Richmond presented the value of 35 days fo potassium on the basis of the daily intake and bod content: 2·6 g and 0·19 per cent of the body-weigh respectively[3]. The value of 2·6 g, which was derive from the observed urinary excretion by E. C. Anderso *et al.*[4], seems surprisingly high as compared with th dietary intakes in Japan.

The value of Q/q in Table 2, namely, the total-bod amount divided by the daily intake, serves for th presumption of total-body burden of a radionuclide an equilibrium is assumed between the human bod and diet. The daily intake of cæsium-137 multiplie by 110 will represent the total-body burden in a long term administration.

This investigation was partly supported financiall by the International Atomic Energy Agency.

BIOLOGY

Depletion of Carbon-13 in Young Kauri Tre

MEASUREMENTS have been carried out of th carbon-13/carbon-12 ratio in a New Zealand kau (*Agathis australis*) a thousand years old. This tre grew in the Omahutu Forest, in the north of Ne Zealand. In 1912 it was felled. The stump, fro which the specimen was taken, suffered in a fore fire in 1931. It is estimated that the fire remove the outer 10–30 growth rings.

Nine samples were analysed for carbon-1 The result of this analysis is shown in Fig. 1*b*, wher $\delta^{13}C$ has been plotted against the age of the sampl $\delta^{13}C$ is defined as the per mille enrichment of th carbon-13/carbon-12 ratio of the sample with respec to that of the P.D.B.-Chicago Belemnite Standard.

In 1954 Craig[1] determined the variation of δ^{13} in a *Sequoia* tree over a different time-interval an noted that the low value found for $\delta^{13}C$ in the youn tree had to be ascribed either to a change in $^{13}CO_2$/$^{12}CO_2$ in air or to differences arising within the tre itself (Fig. 1*a*).

Craig's result for *Sequoia* and the present result fo kauri are similar in shape, but 2,000 years apart i time. They would seem strongly to support a explanation which involves the difference betwee an older and a younger tree, rather than universa changes in the carbon-13/carbon-12 level of the ai

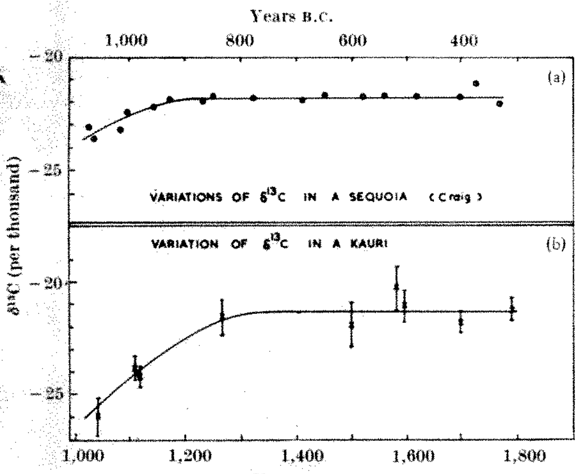

Fig. 1. δ^{13}C-values versus time for kauri (New Zealand) (*b*); and *Sequoia* (*a*).

The depletion in Craig's *Sequoia* is less than that in the kauri specimen described here.

A young tree obtains its carbon dioxide at a lower height above the ground than an older one. On this basis Keeling[2] expects Craig's *Sequoia* to be depleted in carbon-13 in the centre if a local cycling of carbon-dioxide occurs in the area where the tree grows. Whether such an explanation would fit the present results depends on the conditions which prevailed in the area during the period of time when the tree was growing.

However, a *Pinus radiata* from a well-ventilated location in Wainuiomata (near Wellington) was found to have the following δ^{13}C values:

Wood from centre (1880–83): –29·2 ± 0·5
Wood from outside (1955–59): –23·7 and –25·1 ± 0·5

It seems that the only alternative to differences in the carbon-13/carbon-12 ratio of the carbon dioxide absorbed by young and old (or small and tall) forest trees is the existence of differences in fractionation which arises in the trees themselves. For trees growing in exposed areas this interpretation seems to be the only possibility.

I thank Mr. J. R. Hulston of the Institute of Nuclear Sciences for analysing the samples.

Resistance to Aluminium and Manganese Toxicities in Plants related to Variety and Cation-Exchange Capacity

ALUMINIUM and manganese toxicities are now recognized as being major factors in the soil acidity complex[1]. The adaptability of crop plants to acid conditions is of practical interest, and the question arises as to whether selection for persistence on acid soils can be made indirectly via selection for resistance to aluminium and manganese toxicities. Dessureaux[2] has achieved some success in selection for resistance to manganese toxicity in *Medicago sativa*.

Twenty varieties of *Lolium perenne* and *L. multiflorum* were screened for resistance to aluminium toxicity. Twenty seeds of each variety were sown in 800 gm. of silica sand contained in wax cartons (Mono Containers, Ltd.) of 500 ml. capacity, with three replications. The cartons had provision for drainage and were irrigated three times a week with 150 ml. of culture solution : 0·0015 M $(CaNO_3)_2.4H_2O$, 0·00075 M $MgSO_4.7H_2O$, 0·00075 M KH_2PO_4, 0·0001 M $FeC_6H_5O_7$ plus micronutrients and 50 p.p.m. aluminium as $Al_2(SO_4)_3$. Plants were gathered at the end of six weeks, and during the growing period they received aluminium in the culture solution during the first two and last two weeks.

Table 1. RESISTANCE OF RYEGRASS VARIETIES TO ALUMINIUM TOXICITY

S. 101	73	
Danish, early flowering	73	
Sceempter	74	
Kent, indigenous	74	

Table 1 presents the results as percentage decrease in total yield from the control grown without aluminium. It is apparent that wide variation in resistance to aluminium toxicity exists between commonly grown ryegrass varieties. Within most varieties individual plants were found with unusual resistance to aluminium. This suggested the practicability of selection for increased resistance, and from an initial selection of the most resistant plants the 4th selection generation has now been reached. It was found that for later selection generations the concentration of the aluminium in the solution had to be increased.

A less-extensive comparison of ryegrass varieties for resistance to manganese toxicity, using a similar technique, with 25, 50 and 150 p.p.m. manganese as $MnSO_4.4H_2O$, has shown the varieties Heraf pasture and *S*. 321 to be highly resistant, and Melle pasture and Hunsballe late flowering to be susceptible. Selection for resistance to manganese toxicity has also been carried out.

The results in Table 1 suggest that, in general, resistance to aluminium toxicity is independent of geographical origin and hence the soil type on which the varieties were originally developed. This is clearly indicated by the Aberystwyth varieties (with prefix *S*. or *Ba*), which cover a wide range of relative resistance. This conclusion is not surprising, as the soils of plant breeding stations and seed growing farms are unlikely to be allowed to become so acid that high available aluminium becomes a factor in selection. Comparison of the relative resistance of varieties suggests that the annual and biennial varieties tend to show high resistance. This may in part be a reflexion of the normally greater seed size of these varieties, giving more rapid emergence and establishment, as we have indications that seed size and depth of sowing are factors influencing response to screening techniques.

A possible factor in resistance was cation-exchange capacity, and this has been examined. Selections resistant and susceptible to aluminium and manganese toxicities were grown in solution culture with and without aluminium for a period of 8 weeks. Determinations were made on the washed roots using the modified procedure of Crooke[3], and are presented in Table 2.

Table 2. CATION-EXCHANGE CAPACITIES OF ROOTS OF VARIETIES RESISTANT AND SUSCEPTIBLE TO ALUMINIUM AND MANGANESE TOXICITIES

Variety	Root cation-exchange capacity (mean of at least four determinations) m.equiv./100 g dry wt.	
	Control solution	Solution with 15 p.p.m. Al
Danish (susceptible to Al)	23·0	18·7
Ba 7486 (intermediate)	18·5	16·0
Ba 7485 (resistant to Al)	14·9	12·0
	Control solution	Solution with 15 p.p.m. Al
Danish (susceptible to Mn)	23·0	21·7
Ba 8200 (resistant to Mn)	16·2	19·7

It is clearly seen that, of the varieties tested, resistance to both aluminium and manganese toxicities is associated with low cation-exchange capacity. The effect in solution culture of a toxic level of aluminium is to lower the cation-exchange capacity of both resistant and susceptible varieties. Crooke[3] found a variable effect of heavy metal toxicity on cation-exchange capacity, an increase being most common, although manganese caused a reduction.

Data on the cation-exchange capacity of cultivated plants indicate that Leguminosae have approximately twice the cation-exchange capacity of Gramineae[4-6]. Further, that within either major group, species making most demands on soil fertility tend to have a higher cation-exchange capacity than do species less exacting in their requirements. It is possible that the association of aluminium and manganese toxicity resistance with low cation-exchange capacity is an extension of this tendency for plants of low fertility requirement to have a lower cation-exchange capacity. In accordance with the Donnan theory, confirmed by experiment[7-9], low cation-exchange capacity favours monovalent to divalent cation uptake. Thus the lower cation-exchange capacity of toxicity-resistant selections may possibly be effective in increasing the uptake of monovalent cations at the expense of the polyvalent cations aluminium and manganese.

Role of *Dendrophoma* and *Phoma* Species in the Rotting of Jute

IN the course of an investigation designed to investigate the fungal flora growing on jute materials under different conditions of decomposition, species of *Dendrophoma* and *Phoma* were isolated from weather-exposed jute fabric for the first time, using special media. The exposure period was June–August in the monsoon season, and was attended with intermittent heavy rain and sunshine. Isolations were made on 'Cellodextrin' agar and on 'Czapek–Dox'-jute extract agar containing 1 per cent glucose. Similar experiments with conventional media had previously failed to reveal these genera. They were not encountered on jute fabric exposed to 100 per cent relative humidity within the laboratory, nor on fabric rotting in contact with soil or within the bale.

There were altogether four isolates, two of each genus. They are probably different strains of the same species, according to the Commonwealth Mycological Institute, Kew, who very kindly identified the genera. The cultures are being maintained there as *Dendrophoma* 90887 and 90888, and *Phoma* 90889 and 90890.

Phoma species have previously been implicated with the breakdown of cotton fabric on aerial exposure[1-3], and individual species have been shown to cause considerable loss in fabric strength[2,3]. Siu[4] classifies them as moderate decomposers of cellulose. To our knowledge, there is no reference to *Dendrophoma* as a decomposer of vegetable fibres or cellulose, though obviously the two genera are closely related.

Table 1. LOSS OF WEIGHT OF FILTER PAPER

Fungus	Loss (%)
Dendrophoma sp. 192	25·8
Dendrophoma sp. 193	24·5
Phoma sp. 194	21·5
Phoma sp. 195	23·6

Table 1 shows the cellulose-decomposing ability of the four isolates, as determined by loss in weight, after 14 days, of filter paper suspended in 'Czapek–Dox' salt solution. Fig. 1 shows *Dendrophoma* sp. 193 attacking jute fibre.

The organisms form dark-coloured colonies on malt agar, with dark, usually sub-globose pycnidia containing hyaline, elongate spores. *Dendrophoma* sp. 193 tended to form sterile pycnidia after a few transfers on this medium. The cultures are being maintained here on an agar medium containing only jute extract and potato extract, with a strip of filter paper placed

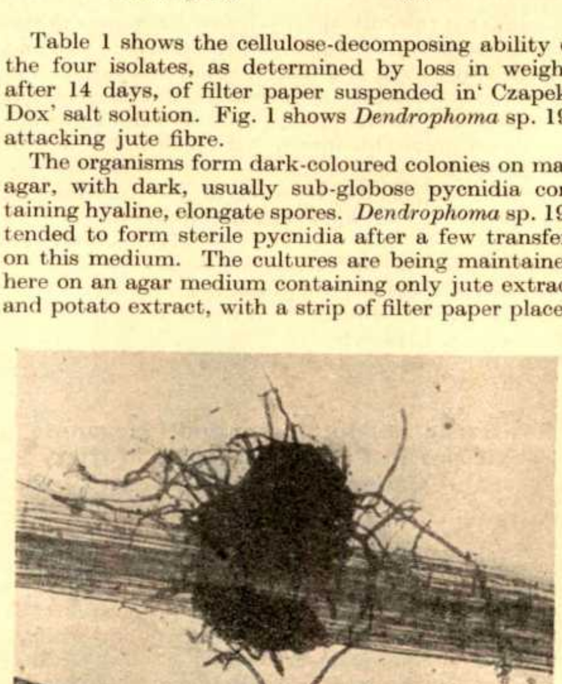

Fig. 1. *Dendrophoma* sp. 193 attacking jute. (× 110)

on the slant. The *Phoma* cultures form heavy mycelial and pycnidial growth on this medium, whereas only pycnidia, concentrated on the paper strip, are seen with the *Dendrophoma* isolates.

'Nests' of the Marine False-Scorpion

During the period April 9–15, 1962, large numbers of *Neobisium maritimum* (Leach) were collected at two places in the Isle of Man, at Chapel Bay, Port St. Mary, and at Port Erin between Spaldrick and Ghaw ny Pharick. All stages, proto-, deuto-, trito-nymphs and adults, were taken from their silken chambers and also collected as free-moving individuals. The silken chambers were preserved irrespective of whether they were occupied or not.

This species has been taken in small numbers in large-scale surveys of the rock crevice fauna at Rhoscolyn, Anglesey[1], and Wembury, Plymouth[2]. The silken chambers ('nests') have been observed by other workers[3-5]. In the Isle of Man both silken chambers and free-moving individuals were most abundant in the outer regions of deep-seated crevices from about high-water springs to the bottom of the *Fucus–Ascophyllum* zone. They have been removed from more shallow and thinner crevices and also from pockets in the mud and sand deposits of the inner regions of the larger crevices.

Table 1

Numbers	♂	♀	Trito-nymph	Deuto-nymph	Proto-nymph	Total
Of free-moving individuals	109	104	25	20	18	276
From silken chambers	6	21	92	80	151	350
Total	115	125	117	100	169	626

It is evident from Table 1 that most of the free-moving individuals were adult while the majority of those removed from silken chambers were nymphs. The adults are distinguished by their genitalia, and the three nymphal stages by the number of trichobothria on the chelæ[6].

The chambers, constructed by individuals of the same stage, vary both in size and shape from almost flat, from narrow crevices, to dome-shaped almost spherical constructions in the wider crevices. It was rare to find them singly (Fig. 1); usually a number were present close together (Fig. 1) or abutting on each other. In one crevice 124 chambers were present on an area 50 cm × 35 cm. Rarely were they applied to both walls of the crevice and normally they were present on the rock wall surface. The examination of one chamber, partially constructed by a tritonymph, suggests that the base is constructed first and the dome built later. The base, however, is not firmly applied and thus the chambers are easily scraped off the rock with a knife. The silken chamber remains complete, and even after long preservation in 70 per cent alcohol with 5 per cent glycerine added, it still retains a small bubble of air. Empty chambers all showed a lateral slit which presumably marks the place at which the pseudoscorpion leaves the chamber.

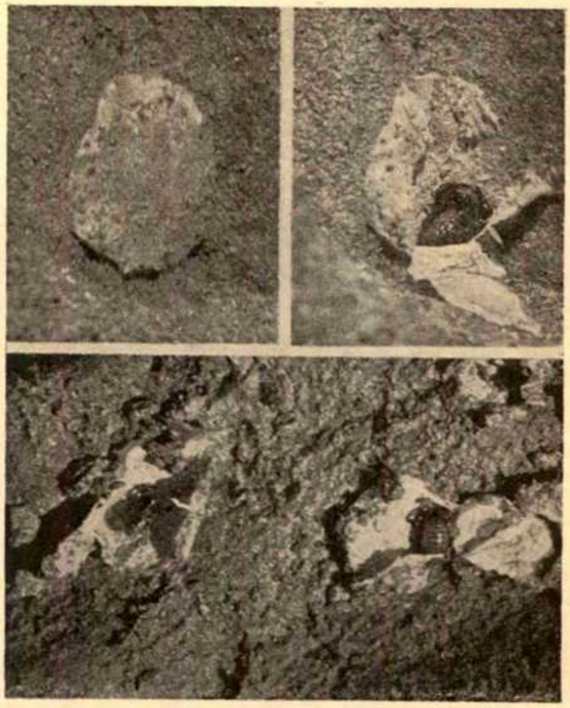

Fig. 1. Top left, silken chamber; top right, same chamber opened to reveal hibernating adult; bottom, two chambers opened to show a tritonymph (left) and an adult (right). (× c. 3)

The new chambers are built of white silk and do not incorporate extraneous matter. They vary from the diaphanous constructions of protonymphs to the dense, stout and tougher chambers of the older stages. Older chambers, mostly vacated, have sand and mud particles adhering to them.

Pseudoscorpions are known to build silken chambers for hibernation, moulting and brooding[5,7]. Of the 794 chambers collected 350 were occupied and each contained a pseudoscorpion. The numbers of each stage are shown in Table 1, and it is evident that these chambers contain a high proportion of nymphs. No brooding chambers (that is, chambers containing females with egg masses attached at the genitalia) were found, and no chamber contained a pseudoscorpion plus its own exuvia. Thus, in the absence of any evidence of moulting, it is concluded that the occupied chambers have been used for hibernation.

All the evidence suggests[5] that each pseudoscorpion builds its own chamber, but in 62 cases these had been constructed within old chambers. The older part often contained the exuvia of the previous inhabitant. Godfrey's[4] observations on the 'nests' of *Chthonius tetrachelatus* (Preyssler) containing apparently a double lining to the wall of the chamber may prove, therefore, to be a misinterpretation.

The unoccupied chambers (444) were divided into those which contained exuviæ (169) and those which did not (275). The trichobothria on the moulted chelæ are distinct, and thus the exuviæ can be allotted to their respective nymphal stages. The difference between exuviæ and dead individuals is difficult to judge, but there is no doubt that most of the nymphal remains are of the former type. The remains of adults proved more difficult. No post-adult moults have been described for this order (although this possibility cannot be completely ignored) and thus these adult remains are more likely to represent individuals which have died during hibernation. In some cases, the shrivelled and withered nature of these adult remains suggests that this is so.

An examination of the unoccupied chambers (169) containing exuviæ and dead individuals revealed that the remains belonged to 30 proto-, 45 deuto-, 66 trito-nymphs and 43 adults (184), the discrepancy in the totals being due to the presence of the remains of more than one stage in a 'double' chamber

The collection of free-living individuals suggests that either the majority of the adults do not build hibernating chambers or that, if they do, they have recently vacated them. Though it is impossible to separate the generations, the high proportion of tritonymph exuviæ suggests that at least some of these adults may have recently moulted. The majority of the nymphs, on the other hand, do build hibernating chambers and the high numbers of protonymphs indicates that some of last year's generation pass the winter in this stage.

Serological Aspects of Immunity in Invertebrates

WHILE most of the scattered attempts to produce antibodies in invertebrates have failed[1], some of the reactions which have been produced in host animals are interesting in themselves. For example, it has been clearly demonstrated that caterpillars develop a temporary, but significant, resistance to bacteria following injections with several kinds of substances[2-4], and that in some cases they even produce heat-stable bactericidal substances[5]. Of great potential significance has been the work of Cantacuzène[6-8], who induced slow antibody-like responses in several marine crabs, in a marine worm, and possibly in an ascidian. His work was done during 1919–28, and therefore lacks some of the quantitative and control data which might fully establish the findings. The findings are of such significance, however, that there is great need to repeat his work and to re-investigate the problem in the same hosts.

During the summer of 1961 at the Station Biologique de Roscoff, where Cantacuzène did most of his work, I examined the responses of the marine worm, *Sipunculas nudus*, and of the spider crab, *Maia squinado*, to a marine protozoan parasite, *Anophrys sarcophaga*. This ciliate is a natural parasite of the shore crab, *Carcinus*, reaches high density in the host blood, and eats the amœbocytes[9]. Ciliates were introduced into the cœlomic cavity of the worm, and the subsequent reaction of the blood to the ciliate studied *in vitro*. Little or no reaction of uninoculated animals was observed after repeated bleedings over a period of five weeks. When, however, the ciliates (in doses of 300 to + 3,000 in 0·2 c.c. of host crab blood) were injected into worms, eight worms produced within 20–48 h a heat-labile substance in the blood plasma which immobilized parasites within 1–2 min. The parasites then lost their cilia, rounded up, and within 10–15 min were lysed so completely that only their outlines remained.

The capacity to destroy ciliates was also provoked in the worm by injections of normal crab blood and of bacterial suspensions. Injection of unsterilized fresh sea-water evoked only a weak and irregular response. Though I tested the sera against *Anophrys* only, the reaction was so readily produced by the several kinds of stimuli that it is probably active against other ciliates as well.

During the process of immunization, or reaction, no change in the *p*H of the blood was observed, and the site of the origin of the substance is not known. It may well be present in one of the numerous cell-types of the cœlomic fluid, and may then be released from such cells by specific stimuli. The lysin is evidently labile, since blood which was positive at the time of withdrawal often lost its activity after standing at room temperature. A positive effect was demonstrated in serum at dilutions of 1 : 20 in sea-water, but under more stable conditions higher titres might be found. 'Immunized' worms maintained a high activity in their plasma for 5–8 days, and then apparently lost it. It reappeared again rapidly following reinjection of the animal. Repeated injection of four worms during a period of 4–8 weeks failed to raise the titre or apparent strength of the activity. No disease was provoked by the injections or bleedings.

The sipunculids, which were obtained from two separate coastal areas, had been kept in the laboratory for periods varying from a few days to several months. Of a total of 82 tested before injection, 10 had slight to moderate 'natural' lytic activity which disappeared within a few days. These positive results in controls may be related to trauma during collecting or to infection which has been recently overcome.

The spider crab, *Maia*, has been described as resistant to infection with *Anophrys*[9]. For this reason the effect of *Maia* sera on the *Anophrys* was studied. Most, but not all, of the spider crab sera immobilized or agglutinated the ciliate within 5–10 min, primarily by causing them to stick to each other by the long tail cilium. Except for further agglutination of the other cilia no other effect was demonstrated and the protozoa remained alive during the several hours of observation. However, 14 per cent (5 of 36) of the crabs completely lacked this protective substance, and when two of these were injected with the ciliates, they rapidly developed a fatal infection, with parasites swarming in the blood. These 'fatal' parasites also were agglutinated by the serum of the resistant animals, but not by the serum of the susceptible crabs. The presence of an agglutinin which immobilized the parasite in most, but not all, cases and which was characteristic for specific animals during the five weeks of investigation, then suggests either that the serum factor is a genetic factor for resistance, or that it is acquired during the course of exposure to the parasite.

These two sets of results suggest that completely different types of protective substances may be found in different invertebrates, and that the presence of the lysin or destructive substance may be evoked in measurable quantities within 1–2 days after the injection of the specific substance or other organic material. The nature of the lysin, the types of substrate on which it is active, and the varieties of stimuli needed to evoke it are unknown.

I thank Dr. George Teissier, director of Station Biologique de Roscoff, for making the facilities available for this research, and for his encouragement during the course of the work.

This work was supported by the U.S. Public Health Service (grant *E*-135); and during the tenure of a John Simon Guggenheim Memorial Foundation fellowship.

Functional Activity of the Anterior Pituitary after Prolonged Cultivation *in vitro* and Transplantation into Pituitary-deprived Female Rats

RELIABLE data on the specific functional activities of the anterior pituitaries which take place during their cultivation *in vitro* are scarce[1–3]. In our previous work we have shown that the infantile rat pituitary kept *in vitro* for prolonged periods and transplanted into hypophysectomized rats will stimulate the growth of the host animal[4]. It is, however, known that for the synthesis of the somatotrophic hormone the anterior pituitary shows a considerable degree of autonomy.

For the examination of the gonadotrophic hormone content, on a biological level in anterior pituitaries after longer periods of cultivation, *in vitro* glands of 3-week-old rats were used. After 21 and 28 days of life *in vitro* the cultivated glands were transplanted into adult (100 g) hypophysectomized female rats. The 3-week-old anterior pituitaries were selected for cultivation after it was established that one whole normal anterior pituitary of this age, grafted in the anterior eye chamber or under the kidney capsule, will cause the appearance of a large number of pure epithelial cells in the vaginal smear of about 50 per cent of adult (2 months old) hypophysectomized female rats.

The cultivation was carried by the watch-glass technique of Dr. H. B. Fell, after the glands had been mounted on a grid of glass rods[5]. The medium used contained rat plasma, chicken plasma and chicken embryo extract in the proportion of 8 : 2 : 6, and the incubating temperature was 33°–34° C.

Following the cultivation, 5 whole anterior pituitaries were grafted in each eye of the host animal, and 3 days later 5 more minced pituitaries were injected into the thigh muscle. (In the course of cultivation the mass of the explanted pituitary undergoes a constant decrease. After 3 weeks of life *in vitro* it becomes reduced to probably no more than a quarter of its original size.) Five to six days following grafting the vaginal wall of 5 of 10 animals (into which 3-weeks-cultivated anterior pituitaries were transplanted) reacted by a sloughing off of a large number of pure epithelial cells. Five host animals did not react. Hypophysectomized rats into which 4-weeks-cultivated anterior pituitaries were transplanted gave no reaction.

The conclusion which can be drawn from this is clear. Fifteen whole pituitaries after three weeks of cultivation contain a sufficient amount of the hormones to stimulate the shedding-off reaction of the epithelial cells of the vaginal wall in the hypophysectomized rat, whereas after 4 weeks of cultivation the amount present in the same number of glands is not sufficient to do it.

The question may be asked whether the hormones eliciting the vaginal reaction have been synthesized *in vitro* or in the host animal following transplantation or whether they had been manufactured in the gland before explantation, stored in the tissue in the course of cultivation, and reintroduced in the hypophysectomized host. The possibility that the hormones are synthesized in the host following transplantation in any appreciable amounts, we believe, can be ruled out, as the vaginal reaction occurs once, and only once. The same is the case when the normal gland is transplanted. It will be more difficult to decide whether the hormones were synthesized *in vitro* or before explantation. The fact that the vaginal reaction following transplantation occurs only once and the glands kept *in vitro* for 28 days gave no reaction speaks in favour of the latter hypothesis. The appearance of the cornified epithelium in the vaginal smear following the grafting of the cultivated anterior pituitaries, at the same time, serves as an index for the presence in the grafted explants of both the follicle-stimulating and the luteinizing hormones[6]. The repeatedly observed failure of the fully developed follicles to give rise to corpora lutea, on the other hand, shows that the quantity of the luteinizing hormone in both the normal infantile and the cultivated pituitaries must have been very small.

In a few cases we injected the medium directly surrounding the explanted pituitary tissue into hypophysectomized rats but without success.

It is worthy of being noted that in the cultures of anterior pituitaries *in vitro* presence of thickly granulated acidophile cells in the explanted gland can be followed for many weeks by means of the Severinghaus technique. With the use of the same technique highly modified basophile cells have been observed after 40–50 days of cultivation, and cells with reduced number of granules up to 30 days of cultivation when the Bodian impregnation technique was applied[7].

Finally, we wish to state that our results obtained on the cultivated *in vitro* rat anterior pituitaries transplanted into hypophysectomized female rats are in complete agreement with those of Cutting and

Lewis[2] on the cultivated rat pituitary transplanted into immature female guinea pigs.

MICROBIOLOGY

Branched and Multiple Forms of *Euglena gracilis*

I HAVE observed in a number of cultures of *Euglena gracilis* (Pringsheim, *Z* strain) organisms of double or branched form having two, four or even eight flagellate anterior ends, these being joined to a central globular structure as shown in Figs. 1 and 2.

Close examination has failed to reveal any dividing wall within the organisms, and the photographs show a dark mass in the central globe which is evidently the nucleus. The multiple forms appear to have arisen through successive cytoplasmic divisions, unaccompanied by nuclear division.

The locomotion of the double forms is erratic, the direction of movement depending on which anterior end may be for the moment in control. The quadrupl and octuple forms are only capable of rolling motio and do not move from place to place through th medium. The causes of the occurrence of these form are not wholly clear, though the presence of a hig concentration of calcium ions has been seen t encourage their development.

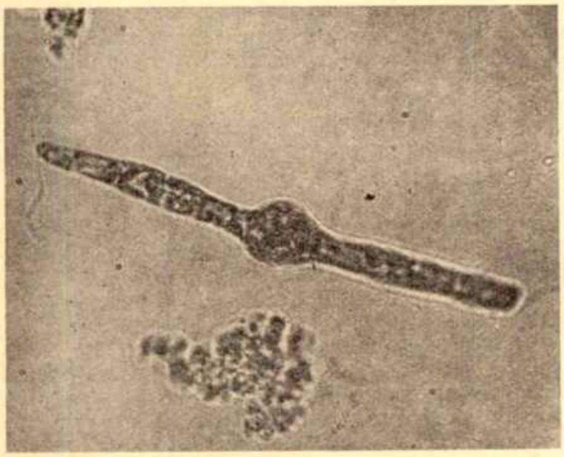

Fig. 1

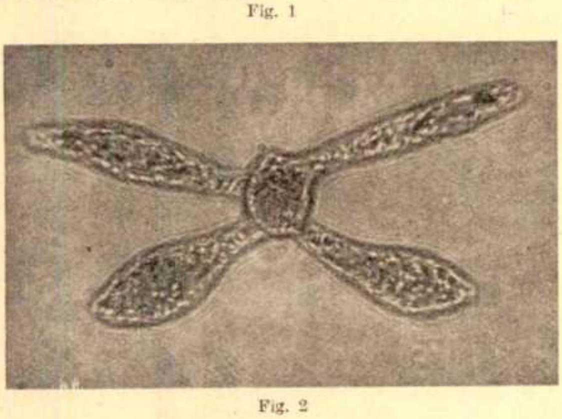

Fig. 2

The double forms of *Trachelomonas* seen b Pringsheim[1] may be a related phenomenon, but h describes these double organisms as having tw (not one) nuclei and nowhere reports quadruple o octuple forms corresponding to those I have seen i *Euglena*.

Lysine Decarboxylase Activity as a Simple Test in Differentiation of Enterobacteriacea

MANY efforts have been made to find simp methods for rapid identification of Enterobacteriacea Most of the tests are based on the ability of tl bacteria to grow on selective media, or to fermer specific sugars, alcohol derivatives, etc. Such tests, i which bacteria are able to grow on selective media, aı usually time-consuming, and positive results aı recorded, at the earliest, only after 24 h.

There are only a few known tests which are base on pure biochemical action between a mass of bacter and a specific substrate. One of these tests is tl ability of *Proteus* species to decompose urea to an monia and carbon dioxide. Such tests give goc results within a few hours. The activity of variou bacteria capable of decarboxylating amino-acids to tl respective amines and carbon dioxide at *p*H ran 4–6 was comprehensively investigated by Gale[1].

Lysine decarboxylase, which is found in variou bacteria and in *Salmonella*, decarboxylates lysine cadaverine and carbon dioxide, usually in acid ran of *p*H. The cadaverine produced shifts the *p*H of tl media towards the basic range of *p*H.

Møller[2–4] tried to adapt ability of *Salmonella* decarboxylate amino-acids for establishing a simp method for identification of the bacteria. By incuba ing *Salmonella* under a paraffin oil layer in a mediu containing lysine as an amino-acid for decarbox ation, he achieved good results within 1–3 days.

Altmann[5] simplified this test by incubating a ma of bacteria in a broth containing casitone, glucose, aı lysine for 2 h, and extracted the amine which w formed by chloroform. By addition of ninhydrin the chloroform containing cadaverine a deep viol colour appeared, which indicated that the bacter strain under test contained a lysine decarboxyla enzyme. By this method all *Salmonella* strains test by him gave positive results with the exception of *S* *paratyphi A.* and *Sal. emek.* On the other hand, *E. coli* strains gave positive results.

Though in the method proposed by Altmann t incubation time is short, the test is rather laboriou and worth while only for differentiation betwe *Salmonella* and *Shigella*; it does not differentia between *Salmonella* and *E. coli* strains.

In order to avoid many preparatory steps, wh maintaining a relatively short incubation time, simplified test is proposed here, based on the fact th in a solution containing 1 per cent lysine in we citrate buffer cadaverine is produced by the splitting of the lysine molecule by lysine decarboxylase, which causes a shift of *p*H towards the basic range. The method used was as follows:

0·5 ml. of 1 per cent L-lysine dissolved in citrate buffer M/2,000 adjusted to *p*H 5·0 and 4 ml. of 0·01 per cent bromo-thymol blue added to 100 ml. of the solution, in serological test-tubes, served as substrate. Heavy inoculum of the bacteria under test taken from a slant by a bacteriological loop served as an enzyme. The test-tubes were kept in a water bath at 37° C for 4 h. By that time, cadaverine that was produced by enzyme action on lysine shifted the *p*H from 5·0 to 6–7, which was seen by the change of the indicator colour from yellow to blue and was recorded as positive.

Table 1. COMPARISON BETWEEN LYSINE DECARBOXYLASE ACTIVITY IN *Salmonella* AND *E. coli*

Strain	μl. Carbon dioxide evolved during 2-h incubation	μl. Carbon dioxide evolved during 4-h incubation
Salmonella paratyphi A	61	111·7
Salmonella reading	156·7	341·7
Salmonella newport	70·6	157·6
E. coli 125	6·0	11·5

The enzymatic system contained equal numbers of bacteria in 0·5–0·1 M citrate buffer in side-arm, 1 per cent lysine in 2·0 ml. 0·1 M citrate buffer in central well; total volume 2·5 ml. Incubation was at 37° C for 4 h. Figures given are after subtracting blanks.

Eighty-eight strains of *Salmonella* were tested, including strains such as *Sal. paratyphi A*, *Sal. paratyphi B* and *Sal. typhi*, with the exception of one *Sal. emek* strain. All the *Salmonella* strains gave positive results; all 13 *Shigella* strains tested were negative; and out of 130 *E. coli* strains tested, all but one gave negative results under these conditions.

All five *Sal. paratyphi A* which were tested gave positive results, indicating that this test is more sensitive than the tests proposed until now.

Though it is well known that many *E. coli* strains contain lysine decarboxylase enzyme, it may be suggested that, under test conditions, the lysine decarboxylase precursor in *Salmonella* is more sensitive than in *E. coli* strains, and causes rapid stimulation of enzyme activity in these bacteria.

In order to check results obtained by this method, three positive *Salmonella* strains—*Sal. reading*, *Sal. paratyphi A*, *Sal. newport*—and one *E. coli* strain were placed in a Warburg apparatus, and manometric readings were taken for 4 h. Output of carbon dioxide was measured, and compared with change in colour occurring in the test-tube.

From the results, which are recorded in Table 1, it can be seen that all *Salmonella* strains were positive and evolved more than 100 µl. carbon dioxide in 4 h, the highest reading being 341·7 µl., while the output of carbon dioxide from *E. coli* was negligible. These values correlate well with test-tube findings.

In conclusion, it is suggested that the method proposed is simple, gives good results in a short incubation time, and enables rapid differentiation between *Salmonella* and other Enterobacteriaceæ.

I thank Miss L. Horenstein of Kupat Holim Laboratories, Haifa, for supplying various bacteria strains.

GENETICS

Temperature Response of the Genetically Stable *R* Locus in Comparison with the Mutable *V* Locus in a Clone of *Nicotiana*

VARIEGATION for flower colour in certain *Nicotiana* cultures results from changes in the functional state of a genetic locus, *V*. The dramatic frequency with which these spontaneous changes may occur in somatic tissue is illustrated in Fig. 1*A*. The germinal changes in state, while potentially reversible, have sufficient persistence to permit their genetic detection by means of altered progeny segregations. Therefore, by genetic criteria, the *V* locus alterations have all of the characteristics of reversible mutations. Each of the functional states appears to possess genetic integrity. The question arises of whether to view these different states as nuclear differentiations or as alterations of genetic code. If the former view were taken, the phenomenon should likely be considered 'paramutation' in the generalized sense utilized by Brink[1].

Although the detailed mechanism is at present obscure, it is of interest to know to what extent the characteristics of unstable genetic systems may be shown also by stable genetic systems. There is evidence from earlier work with the *Nicotiana* material[2-4] for similarities, as well as differences, in response to environmental stimuli applied in common. These and other experiments may elucidate

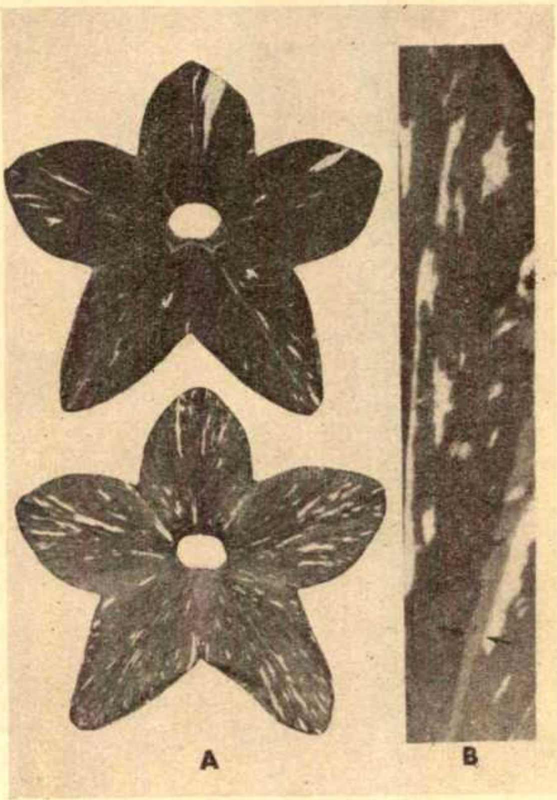

Fig. 1. Flowers of *Nicotiana* clone *S*5230-5: *A*, upper, cultured at 60° F.; *A*, lower, cultured at 80° F. (*c.* × 0·90). The frequency of speckled sectors (associated with the mutable gene *V*) is greater at the higher temperature. *B*, section of petal lobe (*c.* × 4·05) showing (between arrows) a lighter sector of purple tissue (associated with the stable gene *R*) on the background of normally red tissue, which contains more numerous speckled sectors

Table 1. SUMMARY OF SOMATIC AND GERMINAL RESPONSES TO TEMPERATURE FOR BOTH A MUTABLE (SPECKLED) AND A STABLE (PURPLE) GENE IN *Nicotiana* CLONE *S*5230–5. (SEE TEXT).

similarities between mutable and stable genes, and may bear on the broader genetic and epigenetic problem of heritable control over development[5].

The plant material used here is superior to other material for approaching several of these problems experimentally. The origin and genetic behaviour of the variegated cultures have been reported previously[6]. The specific clone used (*S*5230–5) is heterozygous for the mutable *V* gene (v_{s_3}/v_s) and for the stable *R* gene (*R*/*r*), which affect flower colour. Replicated cuttings of the clone were grown at four constant temperature greenhouse conditions: 50°, 60°, 70°, and 80° F. The somatic effect of temperature on the mutable gene system was compared with that on the stable gene system in the same tissue. This was done by counting speckled sectors (changes from v_{s_3} to v_s phenotype, Fig. 1*A*) and purple sectors (changes from *R* to *r* phenotype, Fig. 1*B*) on 126 flower petals from each treatment. Similarly, germinal effects on the same gene systems were studied by counting speckled and purple individuals in progeny obtained after self-pollinating the treated plants. Detailed procedures appear in earlier papers[2,3].

The analysis for somatic scoring and progeny segregation is summarized in Table 1, which presents for the first time the stable gene response compared with the previously published[2] response for the mutable gene. Lines 1–5 of the table show the somatic results for the complete experiment in which sectors were counted within one square centimetre on each petal. Data were taken also to estimate the number of epidermal cells per unit petal area, and permit calculation of 'mutation' rates per somatic cell division for each treatment[2,3]. The average for the stable gene in this experiment is 10^{-6}. However, temperature affects cell size, increasing at higher temperatures the population of cells sampled per cm.^{2}. This leads to the expectation of more sectors per unit area at higher temperatures, even without a direct effect of temperature on the sectoring mechanism. This technical correlation has been dealt with by appropriate analyses of variance and covariance. The results are concisely summarized in the last column of Table 1, showing linear regressions on temperature for each variable.

Results for the final third of the scoring period, after the plants have been longest exposed to the different temperature treatments, are unequivocal, and are given in lines 6–9. Somatic sectoring for both the stable and mutable genes show highly significant, correlated regressions on temperature.

The progeny segregations, observed simultaneously under the same field conditions for all treatments, are given in lines 10–14 of Table 1. No significant temperature effect on germinal response for the stable gene is detected, but final decision is reserved because this consequence could be due to excessive sampling error in the 50 degree point alone. Germinal response for the mutable gene *is* significant and correlated with its somatic response.

The similar somatic responses to temperature for both the *R* and the *V* loci, and their previously reported[4] parallel variation with flower-node position, suggest that stable loci, as well as unstable loci, may undergo heritable changes differentially in varying cellular environments.

Protein Synthesis in Species Hybrids of Birds

THE introduction of the method of starch-gel electrophoresis by Smithies[1,2] has opened up a new field in genetical and phylogenetical studies. Smithies *et al.* showed the presence of a genetical polymorphism in the haptoglobins[3] and the transferrins[4] in man. These findings have already proved to be of genetical and anthropological interest.

Several investigations on apes and monkeys have also been carried out. Thus it is known that lower primates usually have fast-moving transferrin components compared with human beings and chimpanzees[5,6]. In different primate species so far studied, there are generally small differences concerning the main serum protein components. Thus the albumin, cærulo-plasmin, slow α_2-globulin and main haptoglobin (Hp 1–1 band) components show about the same electrophoretic mobility in human beings, chimpanzees and monkeys[5]. The difference between different

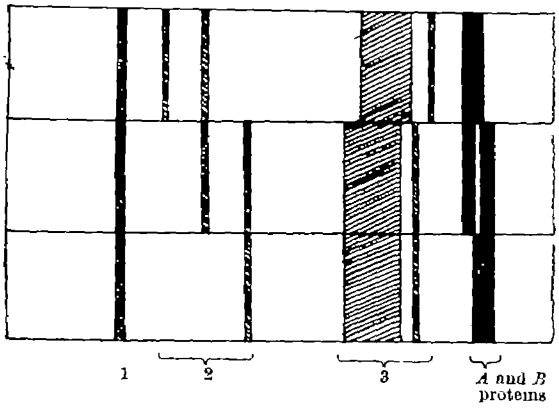

Fig. 1. Schematic diagram showing the main serum protein components in canaries, goldfinches and the hybrids between these two species. Component 1 occurs in all individuals of both species, components 2 and 3 vary within both species and the *A* and *B* proteins are apparently species-specific. Top, *B* goldfinch, middle, *AB* goldfinch × canary, bottom, *A* canary

Macacus species[5,7] is restricted to the presence of different polymorphic transferrin patterns.

From a systematic point of view, it would be of special interest to find qualitative serum protein differences between closely related species. Such differences normally exist between phylogenetically fairly distant groups, for example, between serum proteins of mammals and birds. Qualitative differences between closely related groups have rarely been described. Thus Zweig and Crenshaw[8] have reported differences between turtle species of the genus *Pseudemys*.

We have examined by means of starch-gel electrophoresis the sera of 15 goldfinches (*Carduelis carduelis*), 13 canaries (*Serinus canaria*) and 6 hybrids between these two species. A discontinuous buffer system was used[9]. The serum protein patterns in the two species showed marked similarities, but a difference was observed between the main fast-moving components (proteins *A* and *B* in Fig. 1). All 13 canaries had the fast-moving protein *A* and all 15 goldfinches had the slow component *B*. In the six hybrids both proteins were present, but each was present in apparently half the concentration found in the parental species (Fig. 1). Thus there exists a dosage effect similar to that found in human transferrin heterozygotes.

We have also examined another pair of species, the domestic pigeon (*Columba livia*) and the ring-dove (*Streptopelia risoria*). Fertile male hybrids between these two species are known to exist. The protein patterns of pigeons and ring-doves are rather similar to those of goldfinches and canaries. Between pigeons and ring-doves there was also an electrophoretic difference in the main fast-moving components. We have not yet, however, obtained any serum samples from hybrids between these two species. In view of the interesting results concerning species-specific cellular antigens in doves and pigeons[10], studies of the serum proteins of these species and of their hybrids would certainly yield some significant complementary information.

Sibley and Johnsgard[11], examining avian sera by paper electrophoresis, concluded that serum proteins are of very little value in taxonomic investigations of birds. We think, however, that by the method of starch-gel electrophoresis, investigations of serum proteins of birds may be very rewarding, for example, the use of the *A* and *B* proteins for taxonomic studies in the *Carduelis-Serinus* group.

PSYCHOLOGY

Alternatives in Testing Recognition Memory

RECOGNITION is often possible where recall is not. The inference that memory is superior when tested by the former procedure has been challenged by Davis *et al.*[1], who showed that the number of alternatives from which the items seen previously must be selected was a crucial factor governing performance. When the number in the recognition test is as great as that which could reasonably be considered in recall, recognition performance is no better than recall.

They then analyse their results in terms of the informational measure suggested by Judd and Sutherland[2], on the basis of which they conclude first that the information transmitted in the recognition conditions increases with the number of alternatives, and second that in informational terms recall is at least as efficient as recognition, and in the case of two-digit numbers is significantly better.

We wish to report a demonstration that performance in recognition tests depends not only on the number but also on the nature of the alternatives utilized. It is shown that subjects' incorrect responses are non-random, thus contradicting assumption 7 of the Judd and Sutherland measure, which requires that wrong responses be equally distributed over all symbols.

Fifteen two-digit numbers were presented to a total of 100 subjects at the rate of 1 per 6 sec with an exposure of 5 sec. Two orders of presentation were used, 50 subjects being run with each. Immediately after the presentation was completed the subjects wrote down all the numbers they could remember. Instructions printed on their recording sheets told them that 15 numbers between 10 and 100 exclusive had been exposed.

Errors of intrusion were noted. Two sets of 15 numbers were then drawn from the 74 possible alternatives; one consisting of the numbers which occurred most frequently as intrusions; the other, of those which had occurred least frequently. These two sets were then used as alternatives in two 30-item recognition tests.

Two fresh groups, each of 20 subjects, were given the recognition tests. The 15 items were exposed as before and in the same orders. One half of each group was given recognition tests with frequent intrusions as alternatives; the other halves had a test with rare intrusions as alternatives. The mean number of correct items identified per subject was 10·5 with the former halves, 13·1 with the latter, a difference which is statistically significant ($P < 0 \cdot 01$). For comparison, the mean score per subject in the original recall test was 9·6 items.

Our results indicate that when memory for an item is imperfect the subject is able to identify certain of its characteristics. If a number of items in the set of alternatives from which he has to choose have similar characteristics, then he will be unable to tell which item is new and which has been seen before. If only one has them, then he can correctly identify it. Furthermore, since our results were obtained from a group of subjects rather than intensive study of individuals, there would seem to be some communality in the characteristics used by different persons for encoding numbers in memory.

The *T* Concept

THE concept of tendermindedness has been at the centre of a controversy ever since Eysenck[1] attempted to relate it to political attitudes. First Christie[2] then Hanley and Rokeach[3] sought to discredit the ideas put forward by Eysenck. To some extent the issue has been difficult to settle because there has been no external criterion against which T could be validated. Until now it has been open to whatever interpretation the various parties have cared to place on it. Nor has the scale at present used by Eysenck to measure T ever been factor analysed.

In the present work the T scale was administered to a quota sample of 122 adults obtained from two London boroughs by the random route method. Age, sex, occupation, and political and religious affiliations were also obtained.

Factor analysis revealed the primary component to be a measure of what might best be described as 'moralistic religiosity'. The top-eight items, with loadings from 0·496 up to 0·748, all make direct references to religion, the Church, God, Christ, and life after death. No other religious items appear in the scale. The next ten items all exude a strong moralistic aroma; four are directly connected with sexual behaviour, and the rest are all redolent of moral turpitude in one form or another. These items carry loadings from 0·298 to 0·466 on the primary component.

The last three items, with loadings over 0·200, are of interest in that they have a humanitarian quality and score in precisely the opposite direction to that required by the T concept and the key used by Eysenck. The remaining humanitarian items follow this trend with lower loadings.

To confirm this general finding, religious affiliations were used as an external criterion. Those with religious affiliations scored higher on T than those without, the difference being significant beyond the 0·001 level on a two-tailed test.

Political affiliations follow the pattern built int the scale by Melvin[4], in that there is little to choos between Socialists and Conservatives, while Libera appear higher on T. Previously reported correlatio between Communism and Fascism and toughminde ness are easy to understand in view of the explici opposition of these creeds to the established churc Nor, in the circumstance, is it difficult to believe tha T is correlated with neuroticism as recently reporte by Eysenck[5].

The essential weakness of the T scale as it stands i made clear by comparing Torquemada and Eichman both of whom were noted for their ruthless efficienc and hideous inhumanity. Given his religious affili tions and moralistic fervour, it would have bee virtually impossible for Torquemada to have appeare as other than a distinctly tenderminded soul, despit his authoritarian temperament. Eichmann, on th other hand, although of a very similar dispositio would emerge as extremely toughminded simpl because his particular creed was diametrically oppose to religious dogma other than its own.

R. T. GREEN
B. G. STACEY

Department of Psychology,
University College,
London.

[1] Eysenck, H. J., *The Psychology of Politics* (Routledge, Kegan Pa London, 1954).

[3] Rokeach, M., and Hanley, C., *Psychol. Bull.*, **53**, 169 (1956).

[4] Melvin, D., Ph.D. thesis, Univ. of London (1955).

[5] Eysenck, H. J., *J. Soc. Psychol.*, **53**, 248 (1961).

Green and Stacey strongly support my ow interpretation of 'tendermindedness', as well as givin it statistical backing. In my description in *Psycholog of Politics* (p.132), I wrote: "the tenderminded set opinions appears to be dominated by ethical, mora istic, super-ego, altruistic values". The relationshi with liberalism reported by Green and Stacey also as predicted and found by us. It is difficul therefore, to follow their reasoning when they spea of "the essential weakness" of the T scale. They see to demonstrate this by referring to hypothetic scores on the scale which might be made by To quemada and Eichmann. It need scarcely be sai in a scientific journal that hypothetical data n obtained in an actual experiment but merely postu lated to suit the convenience of the author have litt empirical value, quite apart from the fact that I hav always been at pains to stress that the scale wa relevant only to the country where it was constructe and validated, and only at the time when this proce was carried out; extension of its validity could clearl only be made on the basis of empirical demonstratio I would never have claimed that the scale as it stoo had much relevance to conditions so utterly differe as those obtaining in Spain 300 years ago, and cannot, therefore, regard the hypothetical demonstr tion of Torquemada's tendermindedness as being any way relevant to the argument. Eichmann equally hypothetical toughmindedness I would n wish to doubt, however, although here, too, empiric evidence would be desirable.

Monday, October 8

Plastics Institute, Reinforced Plastics Group (at the Wellcome Building, Euston Road, London, N.W.1), at 4 p.m.—Symposium in "Design Considerations in Three Different Fields".

Institute of Biology (at the French Institute, Queensberry Place London, S.W.7), at 5.15 p.m.—Prof F. Morel (French Centre for Nuclear Studies, Saclay). "Some Aspects of Kidney Function as Revealed by Tracer Studies" (Third Louis Rapkine Memorial Lecture)

British Society for the Philosophy of Science (in the Joint Staff Common Room, University College, Gower Street, London W.C.1), at 5.30 p.m.—Mr. J. R. Lucas: "The One Concept of Probability".

Institution of Mechanical Engineers, Applied Mechanics Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Testing Machines".

Royal Institute of Chemistry, London Section (joint meeting with the Ewell County Technical College Chemical Society, at the Ewell County Technical College, Reigate Road, Ewell), at 7 p.m.—Dr. H. J. Cluley "Complexometric Analysis".

Women's Engineering Society (at "Hope House", 45 Great Peter Street, London, S.W.1), at 7.30 p.m.—Miss A. I. Ross: "Aids for the Disabled".

Tuesday, October 9

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. S. E. Toulmin: "Heresy in Science".*

London School of Economics and Political Science (at Houghton Street, Aldwych, London, W.C.2), at 5 p.m.—Mr. P. O. Lapie "Europe in the Making".* (First of ten lectures on "The Common Market". Further lectures on October 23, November 6, 20, December 4, January 15, 29, February 12, 26 and March 12.)

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers

Society of Chemical Industry (joint meeting of the London Section and the Chemical Engineering Group, at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Mr. C. E. Faulkner and Mr L. E. Parsons: "The Use of Computers for the Control of Continuous Processes".

British Computer Society (at Northampton College, St. John Street, London, E C.1), at 6 30 p.m.—Mr. Saul I. Gass (Washington) "The Role of Digital Computers in Project Mercury".

Institution of Mechanical Engineers, Automobile Division (at 1 Birdcage Walk, Westminster, London, S.W 1), at 6 p.m.—Annual Meeting. 6.30 p m—Mr. H A. Dean "From Headline News to Accepted Practice" (Chairman's Address).

Plastics Institute, London Section (at the Wellcome Building, Euston Road, London, N.W.1), at 6.30 p.m.—Mr. E. C. Bernhardt: "Thermoplastics Processing the Science—the Industry. Recent Advances and Urgent Tasks Ahead".

Royal Institute of Chemistry, London Section (joint meeting with the Brighton Technical College Chemical Society, at Brighton Technical College), at 7 p.m.—Mr R C. Chirnside: "Gemstones and Jewels—Natural and Synthetic".

Royal Society of Medicine, Psychiatry Section (at 1 Wimpole Street, London, W 1), at 8 p m.—Dr. Henry Wilson "Psychiatry and the Medical Registrar" (Presidential Address).

Wednesday, October 10

School of Pharmacy, University of London (in the Assembly Hall, 29–39 Brunswick Square, London, W.C.1), at 8 p.m—Sir Zachary Cope: "The Influence of Pharmacy upon Surgery".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m—Dr. K. A. Kermack "Vertebrate Fossils from Basutoland" (demonstration), Dr. R. Dearnley "The Lewisian Complex of South Harris, with some Observations on the Metamorphosed Basic Intrusions of the Outer Hebrides" (paper).

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, S.W 1). at 5 p.m.—Dr. G. B. Wetherill. "Sequential Estimation of Quantal Response Curves".

British Coal Utilization Research Association (in the Lecture Theatre, Institution of Civil Engineers, Great George Street, London, S W 1), at 5.30 p.m.—Mr. Herbert Seidl: "The Horizontal Cyclone as a Coal Burner" (Eleventh Coal Science Lecture).

Institution of Mechanical Engineers (at 1 Birdcage Walk. Westminster, London, S.W.1), at 6 p.m.—Prof. Kiyoshi Muto, Dr. R W. Bailey and Mr. K. J. Mitchell: "Special Requirements for the Design of Nuclear Power Stations to Withstand Earthquakes".

Society of Environmental Engineers (in the Mechanical Engineering Department, Imperial College of Science and Technology, London, S W.7), at 6 p.m.—Mr. D. M. Corke. "Metal Fatigue".

Institute of Metal Finishing, Organic Finishing Group (at the British Institute of Management, 80 Fetter Lane, London, E.C.4), at 6.30 p.m.—Mr. C. W. Andrews. "Behaviour of Paint Solvents During Evaporation".

Society for Analytical Chemistry (at the Chemical Society. Burlington House, Piccadilly, London, W 1), at 7 p.m—Meeting on "Recent Developments in Polarography". Speakers. Mr. H. M. Davis, Mr. H. I. Shalgosky and Dr. H. W. Nurnberg.

Society of Instrument Technology, Measurement Technology Section (at Manson House, 26 Portland Place, London, W 1), at 7 p.m.—Mr. T. Land and Mr. R. Barber: "Radiation Pyrometry".

Royal Society of Medicine (at 1 Wimpole Street, London, W.1), at 8 p.m.—Sir Stanford Cade, K.B.E., C.B, F.R.C.S.: "Cancer—The Patient's Viewpoint and the Clinician's Problem" (Third Nuffield Lecture).

Thursday, October 11

University College, London (in the Anatomy Theatre, Gower Street, London, W C.1), at 1 15 p.m.—Mr. B. C. Brookes: "The Limits of Human Communication".*

Chemical Society (at the Royal Institution, Albemarle Street, London. W.1), at 6 p.m.—Dr. F. Sanger, F.R.S.: "Amino-acid Sequences in Certain Enzymes" (Pedler Lecture).

Institution of Mechanical Engineers, Thermodynamics and Fluid Mechanics Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p m.—Discussion on "Design of Turbine Stages with Very Long Blades".

Radar and Electronics Association (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7 p m—Dr. K. Milne "Survey of Aerials for Radar and Allied Applications"

Friday, October 12

Association of Applied Biologists (in the Lecture Hall, British Museum (Natural History), Cromwell Road, South Kensington. London, S.W.7), at 10.40 a.m.—General Meeting. Symposium on "Harmful Mammals".

Institute of Physics and the Physical Society, Materials and Testing Group (at 47 Belgrave Square, London, S.W.1), at 11 a.m.—Meeting on "Scattering of Elastic Waves".

Institute of Physics and the Physical Society (at 47 Belgrave Square, London, S W.1), at 2 p m—Meeting on "Space Spectroscopy" Speakers: Dr R. Tousey, Dr J Lindsay, Dr. K. A. Pounds and Dr D. W. O. Heddle.

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof Bengt Stromgren. "Problems of Internal Constitution and Kinematics of Main-sequence Stars" (George Darwin Lecture).

Institution of Mechanical Engineers, Education and Training Group (at 1 Birdcage Walk Westminster, London, S.W.1), at 6 p.m.—Discussion on "Should Engineering Studies be included in Sixth Form Curricula of Grammar and Public Schools?"

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. Konrad Lorenz. "The Function of Colour in Coral Reef Fishes".

Saturday, October 13

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S E.23), at 3.30 p m—Dr Mary E. Gillham: "Some Sea-Bird Islands of the Southern Hemisphere".*

Monday, October 15

Society of Chemical Industry, Pesticides Group (at 14 Belgrave Square, London, S.W.1), at 5 30 p m.—Mr. J. Muir, Mr J. Norris and Mr. K C. Overton. "Determination of MCPA and Related Acids by Gas Liquid Chromatography".

University of London (at Queen Elizabeth College, 61–67 Campden Hill Road, London, W 8), at 5 30 p.m.—Sir Harrie Massey, F.R.S.: "Space Research" (Inaugural Lecture)

Institution of Mechanical Engineers, Railway Engineering Group (at 1 Birdcage Walk, Westminster, London, S.W 1), at 6 p m.—Discussion on "Noise and Railways"

Institute of Metal Finishing (at Northampton College of Technology, St. John Street, London, E.C.1), at 6.15 p.m.—Mr A. Nicholson "Maintenance of Electroplating Plant".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Senior Physicist in the Department of Physics, to be responsible for clinical radiation physics and serve as deputy to the Director of the Department—The Secretary, Board of Governors, Hammersmith Hospital, Du Cane Road, London, W.12 (October 12).

Chief Technician or Senior Technician, to take charge of the glassblowing workshop—The Chief Technician, Division of Chemistry, University of Sussex, Stanmer House, Stanmer, Brighton, Sussex (October 15)

Lecturer in Biochemistry at Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 15)

Research Assistant (with an honours degree in botany or agricultural botany), to investigate the effects of storage conditions on the life-span of crop seeds—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge (October 15).

Scientific Officer/Senior Scientific Officer (with a first- or second-class honours degree or equivalent, with at least three years postgraduate experience for Senior Scientific Officer), to work as an Applied Mathematician or Applied Physicist in acoustics—The Director, National Physical Laboratory, Teddington, Middlesex, quoting N P L. 76 XY (October 15).

Temporary Research Assistant (with an honours degree in chemistry or degree qualifications in chemistry and geology combined, and experienced in silicate mineral and rock analysis) in Geochemistry in the Department of Geology—The Secretary, University College, Gower Street, London, W C.1 (October 15).

Principal Lecturer (specializing in physical metallurgy), a Senior Lecturer/Lecturer in Industrial Metallurgy, and a Senior Lecturer in Mathematics—The Staff Officer, College of Advanced Technology, Gosta Green, Birmingham 4 (October 16).

Principal Lecturer in Mathematics, and a Lecturer in Mathematics (with qualifications and experience to teach mathematics for diploma in technology courses)—The Registrar (Department 25/E), Bradford Institute of Technology, Bradford 7 (October 17).

Demonstrator (prepared to engage in research within the fields of palæontology, stratigraphy or sedimentary petrology) in the Department of Geology—The Registrar, The University, Liverpool quoting Ref. No. CV/181/N (October 20)

Laboratory Technician at Galway Regional Hospital—The Secretary, Galway County Council, County Building, Galway, Republic of Ireland (October 20)

Senior Lecturer or Lecturer in Experimental Physics at the University of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C 1 (October 25).

Senior Lecturers or Lecturers in Experimental Physics at the University of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 25).

Lecturer or Assistant Lecturer in the Department of Geography at Makerere University College, East Africa—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C.1 (October 26).

Lecturer (with special reference to the teaching of science) in the Department of Education—The Registrar (Room 22, O R.B.) The University, Reading (October 27).

Reader (with a Ph.D. in physics or a research record of equivalent level, and preferably teaching experience, or experience in leading research workers) in Physics at the University of Queensland, Brisbane, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Brisbane and London, October 27).

Chair of Pure Mathematics in Monash University, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1; or The Registrar, Monash University, P.O. Box 92, Clayton, Victoria, Australia (Australia and London, October 31)

Lecturer (with an honours degree or a higher degree in chemical engineering, or equivalent qualifications, such as an honours degree in science and Associate Membership of the Institution of Chemical Engineers (by examination), and preferably an interest in thermodynamics or experience in the design and construction of process plant) in Chemical Engineering at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 31).

Senior Lecturer/Lecturer (with at least a good honours degree in agriculture or science, suitable postgraduate experience, and with specialized qualifications in one of the following fields (*a*) agronomy or (*b*) plant breeding and genetics) in Plant Science in the Department of Agriculture, University of Malaya—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W 1 (Malaya and London, October 31).

Senior Lecturer or Lecturer (veterinary surgeon) in Veterinary Medicine—The Secretary, Royal Veterinary College, Royal College Street, London, N.W.1 (October 31).

Lecturer in Education (Psychology) at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 1).

Lecturer or Senior Lecturer (preferably with teaching experience) in Zoology at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 1).

Senior Lecturer (preferably with experience in cardio-vascular physiology or a related field) in Physiology at the University of Sydney—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 9).

Plant Physiologist at the Regional Research Centre, Trinidad (University of the West Indies), to participate in a programme of research on bananas with particular reference to nutrition, timing of crop production and pruning—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 10).

Lecturer or Assistant Lecturer (medically or non-medically or veterinary qualified candidate) in the Department of Histology—The Registrar, The University, Liverpool (November 17)

Lecturer in Pure Mathematics at Monash University, Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 19).

Lecturer (with an honours degree, qualifications and interests in any of the following: plant taxonomy, cytology, genetics, field ecology, and able to teach courses, involving these subjects, to general degree students) in Botany—Head of the Department of Botany University College of Pius XII, Roma, Basutoland (December 1).

Assistant Editor (with good experience of editing professional papers, make-up and progressing, and with some knowledge of engineering or physics) for the *Journal of the British Nuclear Energy Society*—The Secretary, B.N.E.S., c/o Institution of Civil Engineers, Great George Street, London, S.W.1, marking envelope "Staff–Confidential".

Assistant Professor (preferably with a Ph.D. in physiology), of Physiology—Prof. L. B. Lacques, Department of Physiology and Pharmacology, University of Saskatchewan, Saskatoon, Canada.

Grade B Assistant Teacher in the Science Department, to teach physics in O.N C. Applied Physics and Chemistry Courses, and to G.C.E. "O" and "A" levels—The Principal, Reading Technical College, King's Road, Reading.

Junior Laboratory Technician in the Botany Department—The Secretary, Bedford College (University of London), Regent's Park, London, N.W 1.

Master to teach Chemistry with substantial amount of Sixth Form work—The Headmaster, King's College School, Wimbledon, London, S.W.19.

Physics Master, to teach mainly advanced and scholarship level work—The Headmaster, Bishop's Stortford College, Bishop's Stortford, Herts.

Research Student (with an honours degree or equivalent in chemistry, biochemistry or related subject) in the Department of Biochemistry, to work for a Ph.D. degree in the field of the biochemistry of drugs and toxic substances in hens—The Secretary, St. Mary's Hospital Medical School (University of London), Paddington, London, W.2.

Senior Lecturer (graduate) in Animal and Plant Nutrition—The Clerk to the Governors, Essex Institute of Agriculture, Writtle, Chelmsford, Essex.

THE ROLE OF THE INDUSTRIAL RESEARCH ASSOCIATIONS IN BRITAIN

THE major interest of *Research for Industry 1961** lies in the report of the Industrial Grants Committee which, from a policy statement issued with the report, appears to be the full-scale review of the research association scheme which the Minister for Science requested from the chairman of the Council for Scientific and Industrial Research, Sir Harold Roxbee-Cox, last November. Moreover, the policy which it outlines has been fully endorsed both by the Council itself and by Lord Hailsham, who has expressed his satisfaction with the analysis and agrees with the Committee's present policy as set forth in this report. Generally, it endorses the view of the Research Council in its 1958 report that research associations are a valuable investment both for industry and Government, and it emphasizes the importance of keeping the research associations flexible so that they can easily and readily adapt themselves to suit, or shape, the future needs of their industries, and thus ensure that this valuable asset keeps abreast of modern developments and is geared to meet the future challenge.

It is to this end the Industrial Grants Committee reaffirms its opinion that, where they have the facilities, research associations should undertake confidential sponsored work for industry without prejudice to their primary co-operative activities. Direct contact in this way with the problems of firms who know what they want and are prepared to pay the full economic cost to have the work done to their own time-scale can well be, as the Committee suggests, invigorating and rewarding to the staff of the association and possibly strengthen the natural confidence and understanding between the research workers and their industrial clients. Against this, it could involve some difficulties in co-operation in the industry generally, where the competitive spirit is strong, and it is to be noted that when this question of sponsored research was discussed by a group at the Conference on the Pattern of Research in British Industry, arranged by the Federation of British Industries at Eastbourne last April, the view was taken that if such confidential work was undertaken by the research association it should be work in the national interest†. No substantial objection to confidential work as such was advanced because it was held that it was usually only a short time before such work became common knowledge through use. On the other hand, the idea of earmarked sponsored research of a civil nature for the Government was unanimously welcomed.

The Eastbourne Conference was largely based on the survey of industrial research in the British manufacturing industry, which the Federation had previously carried out in collaboration with the National Institute of Economic and Social Research, the results of which were published shortly after Lord Hailsham made his request last November. That report, however, scarcely comments on sponsored research beyond noting the absence of any marked demand for facilities, and although the volume of sponsored research carried out by the associations is growing it still accounts for less than 2 per cent of their income. This compares with about 5 per cent of manufacturing industry's total expenditure on research and development in 1958 in payments to outside bodies such as research associations, independent research institutes and industrial consultants for research services and to other firms for technical knowledge. Since rather less than a third of this went to research associations and most of the remainder is believed to have been spent on such technical knowledge, it is probable that for industry as a whole less than 2 per cent also of the total expenditure was for sponsored work. The Industrial Grants Committee holds that there remains an unsatisfied demand in British industry for such services; by meeting this the research associations could provide a valuable contribution. Incidentally, at the Eastbourne Conference the Parliamentary Secretary for Science seemed to be disturbed that any appreciable expansion in sponsored research by the research associations might adversely affect that in the universities and private research institutes.

The next point made in the report is the importance of a strong and stable research corps supported by adequate funds. Over the ten years covered by the study the cost of research is estimated as increasing by 63 per cent (varying from 41 per cent in engineering to 81 per cent in textiles) and whereas expenditure of the research associations rose by 143 per cent, the growth of research in real terms is put at 52 per cent, varying from 85 per cent in engineering to 36 per cent in textiles and 28 per cent in food. Over the period the total income of the associations increased by 115 per cent, industrial contributions increasing by 133 per cent and the grants from the Department of Scientific and Industrial Research by 53 per cent. In effect, industry has borne the cost of the research growth and part of the increased cost of research, but until 1956 the increase in research barely exceeded that of industrial production and as a whole the research associations have consistently failed to earn the maximum grant offered, the percentage of incentive grant taken up varying between 64 and 76.

† Federation of British Industries. *Pattern of Research in British Industry*. Report of a Conference at Eastbourne, 5–7 April, 1962. Pp. v + 84. (London. Federation of British Industries, 1962.) 5s.

An important factor governing the ease with which increased industrial income and the grant it attracts may be collected is the method adopted by the research associations to assess the appropriate industrial contributions. The Industrial Grants Committee identified 21 different methods of raising subscriptions which may be grouped in six broad categories, of which individual negotiation yields the largest total contribution. Nevertheless, in the general criticisms of research associations made at the Eastbourne Conference, the time spent in raising money figured prominently. It was suggested that there were too many associations and that they might be aligned by disciplines rather than by industries. There was strong support for a fixed Government grant rather than one dependent on industry's contribution.

The Industrial Grants Committee has failed to establish any correlation in the period 1949–58 between the ratio of non-grant to grant income of the associations, age, number of members, expenditure, output of industry and private research by industry. Although there is no statistical evidence that the Government grant determines the pattern of growth of research associations, the grants have manifestly contributed to the initial formation of new associations and fostered reasonable subsequent growth. In recent years, instead of making upward adjustments of the block grant at the beginning of the five-year grant period, the Committee has more often made the adjustment in the middle years, so that associations have had adequate forewarning of the intention to stiffen the grant terms and have been able to plan their budgets to avoid discontinuities of income. Discussions at the Eastbourne Conference can, however, have given the Research Council little fresh confidence as to the effectiveness or the popularity of a policy of stiffening the grant, although the Industrial Grants Committee reports that it has seldom been asked to review grant terms for financial reasons during a normal grant period.

There is a wide variation in the distribution of the effort of the associations between basic and applied research, technical liaison and information. The present average distribution is 23 per cent on basic and 47 per cent on applied research, 18 per cent on technical liaison, and 12 per cent on library and information; in more than half the associations the range in each category is 17–29, 39–55, 13–23, and 9–15, respectively. Most of the associations with low expenditure on basic research serve small industries; those with high expenditure on applied research are large and well established. In an important address at the Eastbourne Conference Sir Harold Roxbee-Cox discussed the role of Government in civil research and development, but his only reference to the support of basic research by the Council for Scientific and Industrial Research related to its research grants to universities and its postgraduate awards. He recognized the problem of financing research associations, but gave no hint of any fresh approach apart from the statement that the Council was looking into the possibility of a system of 'earmarked' grants which will encourage the research associations to undertake projects of direct benefit to the community or industry at large, such as highly speculative projects involving the application of advanced technology, new approaches to productivity, and management studies capable of general application. It is hoped that this type of activity will also strengthen the outstanding terms which are already working in some of the associations' laboratories.

This system of earmarked grants was briefly mentioned in the Council's report for 1961, but it received little notice at the Conference where Sir Owen Wansborough-Jones, reporting on a Discussion Group on the effects of Government contracts on research in industry, referred to what appears to be an alternative method in which the initiative came from industry or the universities. Two research associations collaborated with industry and the universities to examine a problem of interest to all of them, but not of primary interest to any one. A similar example was reported from industry. One of these was concerned with basic problems of oxidation of hydrocarbons and the other with the high-temperature properties of steel. The Group considered that this form of initiative was extremely desirable and would be encouraged if it were known that such initiative was welcomed and had a reasonable chance of Government support.

This appears to be the type of initiative that the Minister for Science is seeking, for in a speech at the Conference dinner, he reiterated Sir Harold Roxbee-Cox's plea for greater support from industry itself and added the warning that industry must also assume greater responsibility for spreading information. Without industrial support it would be necessary to close the information centres started recently in large industrial centres. No indication of this is given in the present report of the Council for Scientific and Industrial Research, and, in view of the meagre information forthcoming on that aspect of the Council's activities, it would seem that the policy is self-defeating, however fundamentally sound is the principle that Government support should be given in response to industrial effort or initiative.

The Industrial Grants Committee's present policy in support of co-operative research is to encourage the establishment and healthy growth of co-operative research programmes for industries or groups of firms who believe that such programmes are necessary The first essentials are the determination of the industrial group to set up a programme, a clear statement of how the industrial finance is planned to increase, and a vigorous director of research. If the scale and quality of the effort proposed are regarded as adequate to maintain a healthy research programme and likely to be further developed, gran support is normally given on a scale designed to produce adequate contributions from industry, and while the proportion of total income derived from Government grant will usually diminish in any individual association, the total grant offered to all research associations has increased each year.

The Committee emphasizes that each individual application differs from the others in some respects and that there is no general formula for assessing the appropriate offer of grant. It is satisfied that the policy of progressively stiffening grant terms to established associations has been reasonable and that industry has rightly accepted responsibility for the major part of the associations' growth. It is also satisfied that the present policy, with the additional flexibility now introduced in such matters as foreign membership and sponsored research, is sufficiently flexible to meet the normal conditions of growth. The initiative rests firmly with the members to ensure that the services are such as will attract the income which will earn maximum grant, make special contributions to the general funds to accelerate parts of programmes of special interest and extend membership, or sponsor confidential work. Beyond this, however, the Committee refers to its recommendation that a new and additional form of 'earmarked' grant should be offered for select projects such as research into aspects of industrial health or safety, research which is to the benefit of the community or industry as a whole, or in further support of outstanding teams the abilities of which can be more widely used.

In all this, however, there is nothing new and no indication of how the problem of finance, for example, is to be more efficaciously or economically handled, or of grappling with these particular problems of improving the research associations which were once again raised at the Eastbourne Conference. More fundamental, in fact, appear to be the Committee's observations on the relations between research associations, universities and technical colleges. There is a reasonably close liaison between research workers in research associations and university departments who are interested in the same or related fields of work, and this has been much stimulated by the appointment of academic visitors to the associations. The associations place work in universities, either by contract or by financing bursaries or research fellowships. There are some joint projects, but although the associations sometimes play a part in postgraduate instruction, planning courses jointly with universities, allowing part of the students' work to be done in their laboratories and supplying external examiners, universities are reluctant to approve external laboratories such as research associations for postgraduate training. There are signs that university regulations are being relaxed, but, although the Industrial Grants Committee makes no explicit statement, it would appear that the major responsibility rests on the universities if full use is to be made in future of the facilities of the larger associations.

If the comments of the Zuckerman Committee on the location of research institutions are fully implemented a decisive change in the attitude of some universities may be required, and the Research Grants Committee of the Department of Scientific and Industrial Research as well as the University Grants Committee should be able to assist to that end. The research associations already give all the help they can to the colleges of technology as well as to the technical colleges, and the inclusion of research associations among the approved industrial organizations in which part of the approved course of study for the new award of Membership of the College of Technologists may be carried out affords a means for even closer collaboration in future. The possibilities of such co-operation will obviously be increased if such a policy of location as the Zuckerman Committee recommends is followed, and it is one which the University Grants Committee as well as the Minister for Science should keep clearly in mind.

It could also be assisted by the greater mobility for which the Eastbourne Conference, as well as the Zuckerman report, called. The desire for greater mobility of staff between industry and the research associations as well as the research stations of the Department of Scientific and Industrial Research and the colleges of technology and the universities was a marked feature of the discussions, particularly the support for permanent part-time appointments to the staffs of universities and colleges of technology of outstanding men from industry. Such a step in itself should help to facilitate co-operation between the universities or colleges and the research associations in different ways; it is obvious that the difficulties are often best overcome when they are considered, as they should be, in the light of Britain's needs for manpower and research as a whole.

The Industrial Grants Committee's report adds nothing to the observations of the Research Council in its report for 1961 on the participation of research associations in operational research and the work of the Industrial Operations Unit, or on the projects submitted by the research associations under the scheme for special assistance to industry. Generally, indeed, it seems to throw little fresh light on the research associations or to offer proposals for making them more effective. Their value in relation to other means of co-operation was more searchingly discussed at the Eastbourne Conference of the Federation of British Industries, but neither the Industrial Grants Committee's report nor that of the Eastbourne Conference on the pattern of research in British industry points to any concrete achievement as a result of the inquiry which the Minister for Science instituted last November.

The great value of the Eastbourne Conference lies in the attention it focused on some vital questions which were left unanswered but demand continuous study. Mr. Aubrey Jones, at the outset, like the Minister for Science, but from a different angle, made the point that the stimulus which Government finance had in the past given to research and development in general in industry was likely to decline. After suggesting that Britain needed to consider impartially the possible limitations of the competitive system from the point of view of research and development, he challenged the amount of effort Britain was putting into basic research. He thought that what was needed was a consideration of whether the broad economic interests of the country required the research and development effort in industry to be more evenly spread, and whether or not the gaps could be defined in Britain's civil effort which it should be the purpose of Government effort to try to fill.

What stands out above all is the need for more fundamental and constructive thinking. This was very evident in Sir Harold Roxbee-Cox's address, particularly in his reference to Government assistance to civil development and the use of civil development contracts. It was made quite clear that the Department of Scientific and Industrial Research is not only reviewing the pattern of the research associations but also that of its research stations. It may well be that policy will not be finally determined nor action taken in advance of the report of the Trend Committee now reviewing the Government organization for science under civil agencies. Meanwhile, the Eastbourne Conference has brought to the front again many of the questions such as the size and organization of firms and research units, the location of research units, the training of managements and the nature of and means for effecting co-operation between industry, Government research stations or departments, the universities and the colleges of technology. The answers to these both determine and are influenced by the character of Government organization—of which, from one point of view, the research association is a part.

JOHN VON NEUMANN

Collected Works of John von Neumann

Edited by Prof. A. H. Taub. Vol. 1: Logic, Theory of Sets and Quantum Mechanics. Pp. x + 654. Vol. 2: Operators, Ergodic Theory and Almost Periodic Functions in a Group. Pp. x + 568. (London and New York: Pergamon Press, 1961.) 100*s*.; 14 dollars each volume.

JOHN (Johann Ludwig) von Neumann was born at Budapest in 1903. His mathematical ability was recognized early, and his father, Max, a banker, made unusual arrangements for his education. Von Neumann's first paper was published before he was eighteen, in collaboration with his tutor, Fekete. While registered for the next four years at the University of Budapest, and taking examinations there, von Neumann was studying at Zurich and Berlin. In 1927 he became *Privat-Dozent* in the University of Berlin and transferred to Hamburg in 1929. He was visiting lecturer in the University of Princeton in 1930, and became a professor there in 1931. Two years later he moved to the Institute for Advanced Study as a professor and held this position for the rest of his life. He became an American citizen in 1937. He died in 1957.

In appearance John von Neumann was on the short side, comfortably tubby in his later life, with a round expressive face. Everybody knew him as 'Johnny'. He was universally liked, and a very large circle of friends remember him with the deepest affection. His thought processes were very quick, and he could speak rapidly in several languages. It was entirely consistent with his personality and his interests that he should be fascinated by the mathematical logic of automata and should foresee the enormous possibilities of such machines.

A tribute to von Neumann appeared in a special memorial number of the *Bulletin of the American Mathematical Society*, (64, 1958) containing eight articles by well-known mathematicians. Groups of his papers are discussed in detail and their place in modern mathematics is assessed. Another authoritative article is the obituary notice by Dr. F. Smithies in the *Journal of the London Mathematical Society*, (34, 1959).

Von Neumann was the author or co-author of several books, on quantum mechanics, on the theory of games and economic behaviour, and on functional operators. His papers are now being re-published as *Collected Works* in their original languages, and where necessary, with errata. Volume 1 covers period 1922–29; and Volume 2 the period 1929–34. The first article in Volume 1 is different in type from all the others. It is called 'The Mathematician' and was first published in 1947. This article is an apposite introductory paper, because it gives von Neumann's views about the nature of the intellectual effort in mathematics.

Volume 1 shows the power and range of the youthful von Neumann. Perhaps the common element is the logical development of theory from axioms with an admirable economy in style and algebraic technique but the creative facility of his mind is being continually revealed.

In 1925 was published the first usable version of the axiomatic theory adumbrated by Zermelo in 1908. The purpose was the same as that of Russell's theory of types, namely to avoid the contradiction of informal or 'naive' set theory. Since the Zermelo–von Neumann theory did not allow the famous Frege–Russell definition of the ordinal and cardinal numbers to be formulated, von Neumann constructed an entirely new theory of the ordinals (1928), a theory now in general use.

The elements of von Neumann's theory of games appeared in 1928. This paper, and the extensions and applications contained in the book with Morgenstern give the mathematical foundations of games of strategy and have influenced all workers in this rapidly growing field. The 'minimax value of a game' and the 'pay off matrix' are deep practical concepts which have been applied in computational programmes illustrating the interplay of economic forces. Although still in an early stage, these investigations are of great interest to those working in the social sciences.

Von Neumann was attracted by the thought of placing the quantum theory on a rigorous axiomatic basis. He saw that the proper framework was Hilbert space; but that it was first necessary to extend and clarify the classification of the linear properties of unbounded operators in unitary spaces. Von Neumann's papers on Hilbert spaces, operator and spectral theory, and rings of operators were outstanding and form a substantial part of his life's work. Volumes 1 and 2 contain his earlier papers in this vast field some of them written in terms of quantum mechanics and some written as formal algebraic studies. Both volumes contain papers on more technical problems in quantum mechanics and statistical mechanics some of the former being written in collaboration with E. Wigner.

Volume 2 contains several papers on measure theory and ergodic theory. Ergodic theory is concerned with the asymptotic temporal behaviour of a conservative mechanical system interpreted by unitary operators in Hilbert space. Although these papers represent only a small part of his total contribution to mathematics, their quality is such that even if he had done nothing else, his place in mathematics would be assured.

A celebrated paper in 1933 solved Hilbert's fifth problem for the compact case and the solution was completed almost twenty years later by others to include the open n-dimensional groups. The question was (in modern terminology) whether in every locally Euclidean topological group there exist systems of co-ordinates such that the co-ordinates of the group-product xy are analytic functions of the co-ordinates of x and y. By an averaging process invented by him, von Neumann showed that the answer is 'yes' for a compact group.

Von Neumann's work on continuous groups include two papers in Volume 2 on almost periodic functions in a group.

Prof. Taub and those who have helped him are to be warmly thanked for editing these magnificent volumes. The publishers are to be complimented on the good printing and the modest price. Although none of von Neumann's papers is easy reading, the importance of his work is so great that these *Collected Works* must be given a place in all libraries concerned with modern mathematics.

Several mathematical colleagues have helped me with advice in the preparation of this review.

W. G. PENNEY

BIOCHEMISTRY OF THE CARBOHYDRATES

Carbohydrates of Living Tissues

By Prof. M. Stacey and Dr. S. A. Barker. Pp. xvii+215. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1962.) 45*s*.

As our knowledge of the chemistry of living matter is extended, a study of the polysaccharide and oligosaccharide complexes present in the animal body is of paramount importance. The present book gives a comprehensive survey of these very complicated materials from the point of view of their known distribution, biological activity, constitution, and chemical properties, together with an account of any abnormalities which are known to occur as the result of a specific disease. The authors are to be congratulated for condensing into some two hundred pages most of the background and modern work on these substances. The bibliographies which conclude each of the chapters are such that the reader is at once presented with the major publications, up to and including 1960.

The first four chapters deal with glycogen, hyaluronic acid, chondroitin and chondroitin sulphate *A*, *B* and *C*, and heparin and heparatin sulphate. Methods for the isolation, fractionation, detection and determination of each of these polysaccharides are detailed, and the chemical techniques utilized in the elucidation of their structures are outlined. The enzymatic pathways, in so far as they have been established, in the biosynthesis and degradation of these polymers are described, and the biological activity of each particular substance is stressed. An account is also given of changes in constitution and amount that occur as the result of a particular disease, and in the case of glycogen this is related to enzymatic deficiencies. The close structural relationship between hyaluronic acid and the chondroitin sulphates is excellently illustrated by the formula on p. 82.

Keratosulphate, mucoitin sulphate, the neutral galactans, and a brief account of the lesser-known sulphated and phosphated polysaccharides, and the constitution, biological activity, and inhibition reactions of the human and cows' milk oligosaccharides form the subject-matter of Chapters 5 and 6.

The last three chapters are devoted to the blood-group substances, to the mucoproteins of blood, urine, saliva, cerebrospinal and other fluids, and to the lipocarbohydrates respectively; in the latter are included the cerebrosides and gangliosides. The authors state that the book is presented only as an interim report, and this is particularly true of a number of substances described in the final chapters of which little is known other than the method of extraction, the constituent sugars and perhaps the biological activity.

The occasional footnote explaining a few of the medical terms could, with considerable advantage to the ordinary chemist, have been increased to include all such terminology, but this is a minor criticism. What is more important is that the book is well written, accurate, and attractively produced with clearly printed structural formulæ.

Inevitably much of the data is presented without comment, but the chief merit of the book is that it brings together a wealth of information which previously has not been collected and which can otherwise only be obtained by an extensive search through the literature. At the published price this book is excellent value, and should immediately appeal to every scientist interested in the operation of the animal body, to biochemists, to research chemists, and to all engaged in the medical profession, particularly those studying chemical changes occurring in living tissues during illness.

ELIZABETH PERCIVAL

ORGANIC AND ENZYME-CATALYSED REACTIONS

Mechanisms of Organic and Enzymic Reactions

By S. G. Waley. Pp. xiii+365. (Oxford: Clarendon Press; London: Oxford University Press, 1962.) 70s. net.

DR. S. G. WALEY has written a book in which the mechanisms of organic reactions and of enzyme-catalysed reactions are discussed together. He starts with molecular structure, and the general principles of mechanistic organic chemistry. He then considers in some detail the more or less usual list of reaction types which have yielded to mechanistic investigation, that is to say, nucleophilic substitutions, olefine-forming eliminations and their retrogressions, carbonyl reactions, saturated rearrangements and electrophilic aromatic substitutions. What distinguishes this from more conventional accounts of mechanism in organic chemistry is the inclusion of reactions, such as phosphate ester hydrolysis, which are of direct interest to biochemists, and of enzymatic reactions themselves. The author has therefore set himself the unenviable tasks of bringing enzymatic reaction mechanisms into the respectable fold of organic reaction mechanisms and, at the same time, of explaining the mystique of the latter to the uninitiated.

Undoubtedly, this is a worth-while and interesting attempt. Students of biochemistry, whose instruction may include little physical organic chemistry, will find a clear although rather elementary account of organic reaction mechanisms, essentially in the spirit of what the Americans call the 'English School'. Chemistry students, on the other hand, will profit from the view that enzymatic reactions are not essentially different, except in complexity, from any other kind and that a study of their mechanisms is both legitimate and potentially profitable.

However, Dr. Waley's approach has its limitations. The hydrolysis of glycosides, for example, is correctly formalized as a nucleophilic substitution on carbon (p. 166). In the context of this book this formulation carries the implications that the criteria which have been so fruitful in distinguishing in simple systems the so-called S_N1 and S_N2 categories, could, in principle, be used for the enzymatic hydrolysis of glycosides and, further, that such a distinction is valid and useful. Both implications may be wrong. In fact, their acceptance leads Dr. Waley to favour Koshland's view that the glycosidases act by producing two configurational inversions, each the result of a simple S_N2 displacement. This may be so, but there is no evidence supporting it. Enzymatic mechanisms cannot be deduced by analogy with simpler systems ; they can only be understood in relation to the structures of the catalytic proteins, a subject which occupies little space in this book.

Nevertheless, Dr. Waley's account could be read profitably by both students of biochemistry and of chemistry. The style is good and clear and the book is well arranged. The price (70s.) however, is to be regretted. Not many students will be able to afford it.

C. A. VERNON

'PARKER AND HASWELL ZOOLOGY' REVISED

A Text Book of Zoology

Vol. 2. By the late Prof. T. Jeffery Parker and the late Prof. William A. Haswell. Seventh edition, revised and largely rewritten by Prof. A. J. Marshall. Pp. xxiii+952. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1962.) 70*s.* net.

It is appropriate that this old favourite, originally written more than sixty years ago by the professors of biology in the Universities of Otago and of Sydney, should be revised and much expanded by an alumnus of Sydney, and should appear as he returns to his own country as professor of zoology and comparative physiology in Monash University, a step in a distinguished career of research and teaching on which all his friends congratulate him.

Prof. Marshall has preserved the general plan of this text-book that has well served so many generations of students, but in his revision he has "attempted to retain basic morphology and yet at the same time emphasize functional aspects and, where possible, present animals as living creatures rather than as laboratory specimens". The strong dose of natural history that he has injected into the book brings it very much to life, and he has followed the lack of solemnity that he admires in Simpson's *The Principles of Classification and a Classification of Mammals* by giving many pieces of out-of-the-way information with characteristic humour—students will surely be glad to find a smile here and there and an occasional broad guffaw in a book so crammed with facts.

The book gains greatly from the criticism and collaboration of a number of zoologists whose names make an impressive list; some of them have contributed authoritative sections on the subjects of their special study. The book is further improved by the expansion of the sections on palæontology in spite of the opinion of some zoologists that the previous edition already carried too much information about fossil forms—"it is impossible to gain a good understanding of living animals, either in form or function without an adequate appreciation of what is known of their ancestry". An innovation is the inclusion of the elements of a classification under many of the illustrations in order to "help the student more or less painlessly to familiarise himself with the animal's systematic position". The student will also be grateful for the lavish cross-reference system so that comparative information can be found quickly and "without tediously repetitive consultation of the Index or Contents".

The book is even more fully illustrated than before; not only are there the familiar figures from Wiedersheim, Owen, Flower and many others but also new figures have been introduced from the works of numerous authors. In addition, the work is embellished with many attractive pen drawings and diagrams by Jane Marshall. These, whether showing living animals or reconstructions of extinct creatures, illuminate the text in more senses than one, but their difference in style from the others gives the volume a certain lack of uniformity that although no detriment is slightly disconcerting to the reader on first perusing it. Perfection is impossible: some misprints have slipped through the proof-reading, and an error of fact appears on page 780—a blue whale yields about 135 barrels of oil, not 1,380, equivalent to about 22½ tons, not six.

The book concludes with an extensive list of references and a copious index. With Prof. Marshall's re-writing *Parker and Haswell* starts a new lease of life and will assuredly well serve further generations of students.

L. HARRISON MATTHEWS

EXOTIC FOREST TREES IN THE BRITISH COMMONWEALTH

Exotic Forest Trees in the British Commonwealth

By R. J. Streets. Edited by Prof. Sir Harry Champion. Pp. xii+765+23 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1962.) 63*s.* net.

Exotic trees play an important part in organized forestry and this is very true of many countries of the British Commonwealth. Plant collectors and travellers were responsible for introducing small numbers of exotic trees which were treated, in most cases, as individuals or small groups, but a landmark in the large-scale use of exotics is the middle of the eighteenth century, when extensive plantings of European larch were made in Perthshire. Since the middle of the past century, the use of exotic forest trees has spread greatly, both for afforestation and re-forestation purposes. The reasons for this are many, but among the main ones are to increase the national forest estate for economic or other purposes, the need to find species suited to the afforestation of difficult sites such as swamps, peat and spoil dumps, and the replacement by suitable, preferably fast-grown, species of degraded forest and woodland lacking produce of merchantable value. Examples are numerous. Of the many coniferous species being used in Great Britain only the Scots pine is indigenous. Exotic conifers, particularly the Monterey pine, play a very important part in New Zealand's forest economy. Almost the entire yield from the forests of the Republic of South Africa is made up from exotic species. Eucalypts have an important role in many parts of the world as exotics, and teak is the most important exotic forest tree used in Trinidad.

A detailed account of the part being played by exotic forest trees in the British Commonwealth is contained in Streets's book. It is based on Troup's classic *Exotic Forest Trees in the British Empire* (1932, Clarendon Press, Oxford) and it has been brought up to date by the reports submitted to the Seventh Forestry Conference of the British Commonwealth in 1957, but a few territories did not respond to the request for information. Mr. Streets has carried out the work of revision and compilation in a most commendable manner and the result is worthy of this important subject.

After a suitable introduction, the information is presented in two parts. Part 1 occupies some 100 pages and it summarizes, according to individual countries grouped in six geographical regions, experience in the use of exotics. This is given under policy, climate, soils, establishment and species. Part 2 takes up the bulk of the volume and in it is described the experience obtained with individual species, listed in alphabetical sequence of generic names. Where appropriate, failure of a species in a particular territory is noted.

Compiler, editor and publisher are to be congratulated in providing a standard work which is very readable, well set out, makes for easy reference and is suitably illustrated. It will readily find its proper place among essential forestry literature.

C. J. Taylor

A NEW BULB BOOK

Collins Guide to Bulbs

By Patrick M. Synge. Pp. 320+56 plates. (London: William Collins, Sons and Co., Ltd., 1961.) 30*s*. net.

Bulbs are Nature's contribution to the pre-packed age: "from no other group of plants", as Mr. Synge observes, "can one obtain a quicker return, since the embryo flower is already present in the bulb when we buy it". Colchicums will flower on the dealer's counter; *Sauromatum* will expand its stinking spathes on the barren expanse of the parlour mantle-shelf, while fragrant paperwhites and hyacinths will survive and give a fair account of themselves in circumstances which would spell instant death to any less tolerant race of plants. Even the choicest and most difficult of bulbs will frequently save the reputations of the vendor and unskilled purchaser by producing a brave show of flowers in their first (and often last) year of trial. Small wonder that bulbs are so generally popular, and small wonder they suffer neglect and maltreatment that would call for instant action by a society for the prevention of cruelty to plants were such a worthy organization to exist.

Mr. Synge's lucid and comprehensive treatise is likely to increase the popularity of bulbous plants, and his sensible advice on bulb-culture may well save many a purchase from an untimely fate. Although the rabid specialist may discover omissions in this book, most readers will find everything they are likely to grow, or wish to grow, in their gardens and greenhouses, as well as descriptions of many rarer subjects, some of them strangers to the pages of our bulb catalogues, and seldom seen outside botanic gardens. The genera and species are arranged alphabetically, which makes for easy reference, even if it offends systematists and sometimes results in the separation of such close allies as *Acidanthera*, *Gladiolus* and *Watsonia*. The text, though of necessity terse, is here and there peppered with personal observations and short digressions that serve to evict boredom, and reassure the reader that the author not only knows, but also grows, many of the plants he lists. The numerous colour illustrations are for the most part excellently clear and informative, though occasionally a little too harsh in tone, so that the lavender-blue *Crocus* threatens to rival *Tecophilaea cyanocrocus* in an excess of brilliance. The glossary and useful bibliography round off a treat, for which, most of us must agree, thirty shillings is a modest reckoning.

R. D. Meikle

NUCLEAR PROPULSION

Nuclear Propulsion

By M. W. Thring. Pp. v+300. (London: Butterworth and Co. (Publishers), Ltd., 1960.) 50*s*.

This book consists of a number of chapters by various authors on themes having some relevance to the problems of nuclear propulsion. There is no introduction by the editor to indicate the plan underlying this collection of articles or the type of reader to whom it is addressed, but it would appear to be a write-up of a set of lectures given to a general technical audience with only a background knowledge of nuclear reactors.

Separate chapters cover the physics and design principles of nuclear reactors and the thermodynamics of jet and rocket propulsion. This is then followed by chapters on nuclear marine propulsion, nuclear aircraft and the nuclear rocket. There is some discussion of materials problems and the book concludes with a chapter on medical and biological aspects of life in sealed cabins.

The range of topics is wide and detailed treatment cannot be expected. More important, the discussion is based on the technology of 1959 and much has changed since then. Although work on the United States nuclear aircraft propulsion project has been discontinued, the nuclear rocket has received increased impetus while the problems of marine nuclear propulsion have continued to receive serious study.

The individual chapters are well written and cover their subjects with admirable compactness. It is a book which is worth reading once, for background knowledge, but it would have been greatly improved if the editor had restricted its scope. There is not a lot in common between the problems of marine and rocket nuclear propulsion.

J. Fell

FURTHER COMMENTS ON ATTEMPTS BY H. MOISSAN, J. B. HANNAY AND SIR CHARLES PARSONS TO MAKE DIAMONDS IN THE LABORATORY

By PROF. KATHLEEN LONSDALE, D.B.E., F.R.S.
University College, London

THE recent successful laboratory crystallization of diamond, in many parts of the world, from carbon dissolved in suitable media under high-pressure, high-temperature conditions has aroused new interest in the attempts made in the nineteenth and early twentieth centuries to make synthetic diamonds. Is it possible that Moissan, Hannay or Parsons really did succeed, in spite of earlier doubts ?

In the case of Moissan and Parsons, none of the specimens they made could be traced after their deaths, although one might have supposed that if genuine, these specimens would have been deposited in the safe keeping of a university or national museum. On the other hand, neither Moissan nor Parsons seem personally to have published any denial of their original claims that they had synthesized diamond. There is, however, plenty of evidence that Sir Charles Parsons was finally convinced that he had never made diamonds; that he realized that his Bakerian Lecture to the Royal Society (1919) was based on an error; and that he took steps to see that a correction *was* published. This evidence I give later on.

The case of Hannay is different. There are, in the British Museum (Natural History), specimens which purport to be the remains of a sample submitted by Hannay to Prof. Story-Maskelyne for examination. These 12 specimens were examined by F. A. Bannister and myself, using X-ray diffraction techniques, in 1942, and the results were first published in *Nature*[1], where various references are given, and afterwards in the *Mineralogical Magazine*[2]. These publications led to considerable correspondence, both published and private, and it seems worth while now to give some extracts from this private correspondence, as well as further X-ray data, obtained more recently, on these 'Hannay diamonds'.

One question that arose was whether in fact the specimens in the British Museum are indeed the remainder of those tested by Story-Maskelyne at Hannay's request. In 1944 I wrote as follows to Dr. E. H. Kraus, who had raised this point: "They correspond exactly to Professor Story-Maskelyne's description of them in *The Times* letter" (February 20, 1880) "and they were labelled in the handwriting of a museum employee who was known to have been most careful and reliable". (This statement was made on the authority of Dr. L. J. Spencer, himself meticulously careful in such matters.) "The fact that there is no other record in the British Museum of a study of the specimens is not very surprising, for at this time the British Museum was in the throes of moving from Bloomsbury to its present quarters in South Kensington, and many records were lost or destroyed. But the existence of the specimens themselves is, of course, listed in the records, and from that point of view they are as authentic as any of the other specimens of that time."

The X-ray diffraction studies made by Dr. F. A. Bannister at the British Museum in 1942 established beyond doubt that 11 of the 12 tiny British Museum crystals were diamond, and my more detailed X-ray study of one of them, using the powerful 5-kW equipment at the Royal Institution, proved that it was a type II diamond (that is, that it did not show 'extra spots' regarded as typical of type I). The British Museum authorities were naturally not willing to allow all these unique specimens to be removed from the Museum for individual and prolonged testing during the uncertain conditions of war-time; and our investigations therefore ceased at this point. At the time it was believed that type II diamonds were very rare and that even if only one out of the eleven 'Hannay diamonds' were of type II that would be strong presumptive evidence that they were synthetic and not natural. On April 5, 1943, I wrote to Lord Rayleigh: "If type I diamonds are 'perfect' (in the X-ray sense) and type II diamonds are 'mosaic' in structure, as all our experiments seem to indicate, then it is fairly certain that if and when a reliable laboratory method of making diamonds is discovered, it is type II diamonds that will be obtained, since no laboratory experiment can ever hope to reproduce the ideal 'annealing' conditions found in Nature's workshop in the depths of the earth". By this time, however, I was not so sure of the *rarity* of *natural* type II diamonds, for in the same letter I wrote: "I am now coming to the conclusion that diamonds giving type II effects are perhaps not so rare as was formerly supposed. It is true that in one parcel of 500 diamonds that I have recently examined with a direct vision spectroscope, only one was transparent beyond λ3000, but on the other hand two much smaller assortments of industrial diamonds contained some 50 per cent type II specimens". Later on, Dr. H. Judith Grenville-Wells[3] found a high proportion of type II (by a study based on ultra-violet transparency) in a collection of 175 *small*, good natural diamonds. Recently, Dr. Milledge (formerly Grenville-Wells) has examined two more of the British Museum 'Hannay diamonds' and has found that these do show the 'extra spots' typical of type I. It is clear, therefore, that this part of the evidence is no longer a point in Hannay's favour.

Two questions then arose: whether other evidence of an 'internal' nature could be found that would suggest whether these diamonds were natural or synthetic; and whether Hannay himself was trustworthy ? It is easier now to deal with the first of these two questions. All the diamonds recently synthesized, and studied by us, have been rather imperfect. They have all given diffraction patterns on which some spots are poorly shaped and on which there are definite signs of distortion. So far we have found none of type I, and attempts are at present being made to determine the source of the type I diffraction phenomena by the 'doctoring' of synthetic diamonds under controlled conditions—as yet without success[4]. We understand that there are now synthetic diamonds made which do have good morphological habits, but we have not yet had the opportunity of studying their X-ray diffraction (Laue and diffuse) patterns. Unlike the synthetic diamonds which we *have* studied, the 'Hannay diamonds', although laminated and splintery in appearance, give very good, clean diffraction patterns without much 'spot distortion'. They do, in fact, give just the kind of diffraction pattern which would normally be expected from splinters of natural diamond. If my opinion were now asked, I would be bound to say that I think that the 'Hannay diamonds' *are* splinters of natural diamond, or at least that there is no 'internal evidence' to the contrary.

The question of Hannay's trustworthiness is far more difficult to answer. As Lord Rayleigh wrote to me (November 26, 1943): "Some people at close quarters with Hannay seem to have been convinced of his good faith. On the other hand, you will probably agree that there was a formidable array of instructed opinion that disbelieved". This current disbelief seems to have been based on the inherent unlikelihood that a young man of twenty-four years of age (as he was in 1879), a chemical engineer without a formal training in physics, could have succeeded in what was, after all, a very empirical 'long shot' experiment, however persistently repeated; and also on some fully justified criticism of some of his other published work, criticism which he never attempted to refute. Lord Rayleigh, in a letter to *Nature*[5], mentions also a paper by Hannay that was rejected by the Royal Society, but there is no mention in the Royal Society records of such a paper. I am informed that if submitted at all, it would have been recorded, even if rejected. Later disbelief has been based on the failure of all attempts to repeat Hannay's experiments under the conditions that he described. In a sense, however, this particular criticism is discounted by the fact that he claimed success in only a very small percentage of his own experiments, added to the difficulty of repeating experiments with materials precisely similar to those available more than eighty years ago. It seems, therefore, that the diamonds in the British Museum are almost certainly natural diamonds; but whether Hannay himself knew this is uncertain, and will probably never be proved.

The case of Moissan is somewhat parallel except that no 'internal evidence' is available since no specimens are available. His methods have been repeated many hundreds of times without the formation of any diamonds. I recently inquired of Prof. J. Wyart, head of the Department of Mineralogy and Crystallography at the Sorbonne, whether he could supply me with any further information, for possible publication, about Moissan's experiments. He replied as follows:

"Dans le Laboratoire de Moissan, il ne reste aucune trace de l'appareil et des cristaux de diamant. Henri Le Chatelier, qui a été son successeur au Laboratoire de Chimie générale, ne croyait pas au diamant de Moissan et dans son livre 'Science et industrie' (Flammarion, 1925) il dit à la page 195: 'Personne ne croit plus au diamant de Moissan; même de son vivant, en dehors de ses élèves, peu de savants ont pris au sérieux cette prétendue découverte.' Cette opinion de Le Chatelier était aussi celle de F. Wallerant, qui occupait la chaire de Minéralogie de la Sorbonne et qui a été mon premier maître. Il avait vu les diamants de Moissan, et Wyrouboff, très connu pour ses travaux de chimie et de cristallographie, qui travaillait à coté de Wallerant, les avait soigneusement examinés au microscope polarisant. Il en avait conclu que les cristaux de Moissan n'étaient pas du diamant."

The possibility that Sir Charles Parsons had made diamond was far more intriguing. In his Bakerian Lecture to the Royal Society (1919) Sir Charles described various experiments in making diamonds, some of which he claimed were successful, and added: ". . . nothing was obtained of interest with the substances used by Hannay unless, as previously mentioned, some iron was present". This implied that something "of interest" was obtained in the presence of iron. Yet in a letter to *Nature*[6], Lord Rayleigh stated that Sir Charles Parsons had repeatedly conversed with him on the subject of his experiments and had told him that the crystals obtained would not burn in oxygen and therefore were not diamonds.

An article on "The Problems of the Artificial Production of Diamonds" had appeared in *Nature* in 1928[7] signed "C. H. D.", summing up the case for believing that up to that time no diamonds had ever been made in the laboratory. I corresponded with the author, the late Dr. C. H. Desch, and received a letter from him dated November 3, 1942, in which he wrote: "When Sir Charles Parsons had repeated his experiments and had concluded that the crystals which he at first obtained were not diamond he sent me all the notebooks and also his correspondence with the French people who had known Moissan. It seems that Moissan was in bad health in his later years and never made any satisfactory examination of the crystals . . .". Dr. Desch also referred me to Sir Charles Parson's assistant, the late Mr. H. M. Duncan, with whom I had considerable subsequent correspondence. Mr. Duncan gave me permission, in a letter dated March 16, 1944, to mention his name as having supplied me with information about Sir Charles Parsons's experiments on the manufacture of artificial diamonds.

I had been impressed by the fact that Hannay had claimed that his only successful experiments were those in which lithium was included in the mixture. (Lithium and diamond have rather similar lattice constants, 3·509 and 3·567 Å respectively, although Hannay could not possibly have been aware of this fact, which is given by the results of X-ray structure analysis. Lithium is, however, a body-centred cubic structure and diamond a face-centred cubic one.) H. M. Duncan's comment on this (June 17, 1943) was ". . . for many years the late Sir Charles Parsons and I repeated not only Hannay's experiments but also Moissan's over and over again without success, and I can assure you that we very frequently used lithium. . . . When I joined the late Sir Charles Parsons in 1911, he was quite satisfied that he had succeeded in some of his experiments in producing artificial diamond, and naturally I accepted his conclusion and so all our experiments were conducted on the lines which he had thought successful and although at the time of the reading of his paper before the Royal Society (1919) he still held this belief, I was convinced in my own mind that the results which he had obtained before I joined him were very doubtful, more especially since all the experiments in which I took part, although they were conducted with the greatest care and patience, were unsuccessful, and by constantly suggesting to him that he may have been mistaken in the past, he at last decided to test, by burning in oxygen, the characteristic crystals which he had carefully mounted on slides, and it was a bitter blow to him when he found that they would not burn". He went on in a subsequent letter (June 25, 1943) to explain that "the method adopted of burning in oxygen before I joined the late Sir Charles Parsons was very crude and . . . I doubt whether a sufficient temperature was attained to burn the real diamond. . . . It was only after many years of arduous work and continuous doubtings of our results that I tried an experiment of introducing a platinum boat, carefully cleaned, into the furnace with oxygen passing through it and at the required temperature; on the introduction of the boat numerous flashes were observed similar to the ones we had obtained in our experiments. This naturally gave the late Sir Charles Parsons quite a shock and although he said very little at the time he thought it over for many days and at last decided to burn the characteristic crystals which he kept at home . . . on withdrawing the boat and re-examining under the microscope, the characteristic crystal was found untouched". On July 19, 1943, Mr. Duncan wrote: ". . . I remember Sir Charles telling me that he had consulted the President of the Royal Society as to the best means of acknowledging that he was mistaken. I prepared a statement, which was given to Dr. Desch and from which he prepared the letter [this was in fact the article referred to above. K. L.] published in *Nature*. With regard to the characteristic crystals, I can tell you that these consisted of magnesia and alumina. . . .".

It seems worth while to publish the relevant parts of this correspondence because Dr. Desch's first article did not make it really clear that Sir Charles Parsons himself had inspired it, desiring by this means to withdraw his previous claim. In a second article in *Nature*[8], Dr. Desch made this much more explicit, but added the suggestion that the X-ray identification of the Hannay specimens as being diamond might re-open the whole question. The near-certainty that these Hannay specimens are *natural* and not synthetic diamond, however, restores the *status quo* and makes me believe that neither Hannay, Moissan nor Parsons ever, in fact, made diamonds by their respective methods; although whether the claims of the first two were made in good faith throughout (as Parsons's certainly were) is more difficult to judge.

EFFECT OF ULTRA-HIGH VACUUM ON *BACILLUS SUBTILIS* VAR. *NIGER*

By FRANK A. MORELLI
Space Sciences Division
AND
FRANCIS P. FEHLNER and CHARLES H. STEMBRIDGE
Physical Sciences Division, Jet Propulsion Laboratory,
California Institute of Technology, Pasadena

THE effects created by exposing organisms to a vacuum have long been a subject of interest to biologists[1]. The use of a vacuum in storing micro-organisms is an essential part of lyophilization preservation technique[2]. In this method, the organisms are frozen at −80° C and dehydrated by a vacuum of 10^{-3} mm mercury. The tubes containing the organisms are sealed off under vacuum and may be stored for several years.

An investigation was carried out by Bakanauskas[3] to determine the effect of a prolonged dynamic vacuum on the viability of selected spore-forming fungi and bacteria. The micro-organisms *Aspergillus niger*, *A. flavus*, *Bacillus globigii* (*B. subtilis*), *B. mycoides*, and *B. cereus* were exposed to pressures ranging from 1×10^{-5} to 5×10^{-7} mm mercury for periods of 2, 4, 8, 16, and 32 days. With the exception of *Bacillus cereus*, all the micro-organisms remained viable after 32 days exposure.

Despite these results, the ability of micro-organisms to withstand ultra-high vacuums of the order of 10^{-8} mm mercury or better has been questioned. Brueschke, Suess and Willard[4] report that exposure of micro-organism spores (*Bacillus subtilis*, *Aspergillus niger*, *A. terreus*, and *Penicillium citrium*) to pressures of $1{\cdot}2 \times 10^{-8}$ mm mercury and lower for a sufficient period of time (greater than 10, but less than 31, days) will cause their destruction. However, recent work by Portner, Spiner, Hoffman, and Phillips[5] failed to show any effects of vacuum on three types of micro-organisms (*Bacillus subtilis*, *Aspergillus fumigatus*, and *Mycobacterium smegmatis*) exposed to a vacuum of less than 10^{-9} mm mercury for 5 days. The work reported here seeks to verify one of these conclusions for the micro-organism *Bacillus subtilis*.

An apparatus was constructed from 'Pyrex' glass to expose simultaneously eight micro-organism samples to a vacuum of 10^{-8} mm mercury or better. It consisted of a round bulb having eight sample tubes (3 cm. × 1·5 cm.) on the bottom, plus a break-seal vent and entry port on the top. An ion gauge (Bayard–Alpert type) was mounted opposite the pump connexion to provide pressure readings at the point of poorest vacuum.

The ultra-high vacuum was obtained with a double-trapped (liquid nitrogen) three-stage mercury diffusion pump. To ensure that mercury would not contaminate the high-vacuum region, a gold plating was so placed that molecular backstreaming from the region of the pump and traps was intercepted and the mercury vapour was held by amalgamation. In order to minimize outgassing from the glassware in the high-vacuum region, it was cleaned with hot nitric acid. After a rinse with distilled water the apparatus was dried and the gold plating was applied by vacuum deposition.

Table 1. RECOVERY OF *Bacillus subtilis*

Inoculum count (micro-organisms)	Bacteriological recovery from controlled room-temperature atmosphere 1	2	3	4	5	6
30	22	49	80	144	53	60
30	14	78	82	82	64	48
300	135	158	150	143	126	120
300	135	156	167	109	139	138
3,000	150×10^1	500	1,410	1,500	1,140	1,080
3,000	138×10^1	1,700	1,580	2,500	1,090	1,910
3×10^{5}*	142×10^{3}*	107×10^{3}*	152×10^{3}*	78×10^{3}*	44×10^{3}*	143×10^{3}*
3×10^{5}*	142×10^{3}*	142×10^{3}*	190×10^{3}*	63×10^{3}*	41×10^{3}*	149×10^{3}*

1, Ultra-high vacuum for 35 days; 5 min of 25-kc/s ultrasonic agitation.
2, Slight vacuum (300μ of air) for 36 days; 5 min of 25-kc/s ultrasonic agitation.
3, Nitrogen at 1 atm. for 38 days, 3 min of 25-kc/s ultrasonic agitation.
4, Argon at 1 atm. for 38 days, 3 min of 25-kc/s ultrasonic agitation.
5, Carbon dioxide at 1 atm for 38 days, 4 min of 25-kc/s ultrasonic agitation.
6, Air at 1 atm for 38 days; 4 min of 25-kc/s ultrasonic agitation
* Average value of 3 counts.

The pressure in the high-vacuum region was monitored by the Bayard–Alpert-type hot-filament ionization gauge. An initial vacuum of 3×10^{-6} mm mercury was obtained. This fell to 1×10^{-8} mm mercury after 15 days, and to a final value of 6×10^{-9} mm mercury after 35 days. The lowest pressure which can be measured directly with this type of gauge is approximately 5×10^{-10} mm mercury.

The samples of *Bacillus subtilis* were prepared, introduced into the vacuum apparatus, and recovered in the following manner. One ml. of a stock culture of an aerobic spore former, *Bacillus subtilis* var. *niger*, was diluted by adding 99 ml. of sterile distilled water. The suspension thus formed was placed in a 60° C water bath for 30 min to kill vegetative organisms. Average control counts of the remaining spores diluted 10^5 and 10^6 were each made in triplicate. Average values of 35×10^6 and 329×10^5 organisms per ml. were found. Further dilutions were so arranged that inocula containing 300, 3,000, 30,000, and 3×10^6 organisms per ml. were obtained.

Each of the eight sample tubes attached to the apparatus was then inoculated with 0·1 ml. of inoculum as delivered through the entry port by a tuberculin syringe and needle. After seal-off of the entry port, a slight vacuum (about 20 mm mercury) was pumped, and the water in the cultures was allowed to evaporate. The sample tubes were immersed in a pan of warm water to prevent freezing of the microorganisms during this drying process. As soon as the water in the cultures had been removed, an ultrahigh vacuum was applied to the spore samples.

The micro-organisms were sealed off from the vacuum system at the end of the 35-day period. The chamber was brought to atmospheric pressure by opening the break seal and allowing air to flow through a 4-in. plug of sterile fibreglass. Two ml. of sterile distilled water were added to each sample tube through the entry port and the whole apparatus was placed in a 25-kc ultrasonic transducer. Vibration for 5 min (with the entry port closed) sufficed to remove the micro-organisms from the glass and disperse them into the distilled water. These suspensions were aseptically transferred into sterile Petri dishes. Warm trypticase soy agar was then added and the mixtures were allowed to solidify into pour plates. All pour plates were incubated at 37° C for 5 days before counting was carried out.

Control samples were prepared from 0·1 ml. of each of the inocula containing 300, 3,000, 30,000, and 3×10^6 organisms per ml. The suspensions were pipetted into test tubes, dried under vacuum in a bell jar, and placed in room-temperature desiccators, each of which contained one of the following atmospheres: (1) air at 300μ; (2) nitrogen at 1 atm.; (3) argon at 1 atm.; (4) carbon dioxide at 1 atm.; (5) air at 1 atm. The control samples were recovered and counted in the same manner as the specimens exposed to ultra-high vacuum.

Table 1 lists the bacteriological recoveries from controlled atmospheres at room temperature. In all cases, experimental as well as control samples, approximately half the micro-organisms were recoverable.

The deviations in tabulated counts are within the range expected for a biological experiment. Spurious results were obtained with the inoculum containing 30 organisms, for more organisms were recovered than were thought to have been in the original sample. However, these counts are not considered significant because they reflect the magnified errors encountered in working with low concentrations of micro-organisms. Samples containing statistically significant numbers of micro-organisms produced consistent data.

The results shown in Table 1 demonstrate that spores of *Bacillus subtilis* var. *niger* will survive exposure to an ultra-high vacuum (10^{-8} mm mercury) for a period of 35 days. The experiment also shows that ultrasonic vibrations and radiation encountered during seal-off of the apparatus have no significant effect.

Since the results of this work completely contradict the conclusions reported in ref. 4, further work on the problem is anticipated. An apparatus is under construction which will produce and directly measure pressures to 10^{-10} mm mercury. Even though a decrease in pressure from 10^{-8} to 10^{-10} mm mercury (which lengthens the average mean free path of a gas molecule from 5×10^5 to 5×10^7 cm) is of little significance in an apparatus having a radius of 12 cm, it will be interesting to expose *Bacillus subtilis* to a vacuum approaching that encountered in outer space. A second experiment will involve exposing a non-spore former and an anaerobic spore former to a vacuum between 10^{-8} and 10^{-9} mm mercury to determine whether the resistance of these forms to ultra-high vacuum is as great as that of aerobic spores.

This work was carried out under contract No. *NAS* 7–100 sponsored by the National Aeronautics and Space Administration.

NEW RADIOCARBON DATES OF NILE SEDIMENTS

By PROF. RHODES W. FAIRBRIDGE

Columbia University, New York

IN the present Unesco "Save the Nubian Monuments" campaign, it is most fortunate that the Palæolithic works of man along the middle Nile Valley have not been forgotten. The construction of the Saad el Aali, the Aswan High Dam, will drown a 500-km long sector from the First Cataract (Aswan) almost to the Third Cataract (considerably south of Wadi Halfa). This sector contains a unique record of Nile sediments that not only spans the history of man from early Christian and Dynastic times back to the Palæolithic, but also sheds considerable light on the complex problem of climatic change in Africa, indeed, on the world problem of climatic change.

I was fortunate in being invited to lead a Columbia University expedition to Nubia in the winter of 1961–62, jointly organized by the Departments of Anthropology (under Dr. Ralph Solecki) and Geology (myself), and sponsored by the National Science Foundation, Washington. It is a pleasure to record the friendly co-operation of all officials in the Sudan, which helped to bring this mission to a successful conclusion. The geological–palæoclimatical results will be briefly reported here.

Unique Position of the Nile

The Nile occupies a unique place in the geographical world, since its net flow reflects the average precipitation over a large area of equatorial Africa. Running northwards through totally arid Nubia to the temperate Mediterranean, its sediments are not confused by local complications; its middle and lower courses are devoid of flowing tributaries. In the Nubian sector, therefore, the Nile is a sort of 'tide gauge' of tropical rainfall.

The older sediments should also reflect the ancient equatorial climates. If we could date these sediments, we would be in a position to relate tropical climates to events of the late Ice Age. The question was, how to date them. It seemed to me that there were basically three methods available:

(*a*) *Human artefacts*. The cultural relics of Stone Age Man provide a broad basis for dating the fluvial terraces; but they are not precise 'fossils', and there are sources of possible confusion.

(*b*) *Ancient shorelines*. Around the Mediterranean the old beaches of former ocean-levels are approximately dated, not at all well, but at least the rough sequence is established. These shorelines can be related to the river terraces; the latter are 'thalassostatic' in their lower reaches, but above the First Cataract, the oceanic influence disappears.

(*c*) *Radiocarbon dating*. Material for dating might include fossil wood, charcoal from human camp sites, and the calcium carbonate shells of fossil Mollusca. I was very dubious at first about finding adequate shell horizons, but discoveries of these freshwater shells at all the critical levels surpassed my wildest optimism. We now have radiocarbon dates which bring the whole sedimentary régime into mass time perspective.

Theory of Pluvial Climates

Until very recently an unresolved controversy existed as to the causative nature of ancient climatic changes. According to Sir George Simpson, an increase in solar radiation should lead to increased evaporation from the oceans, and thus to increased precipitation, which would become critical in high mountain areas, where it would fall as snow, eventually to develop into great icefields. By various meteorological feed-back mechanisms an ice-age would result. This theory is now generally recognized to rest on completely false premises; to begin with, polar ice-caps are cold deserts, lacking significant precipitation. Ahlmann has shown that it is the mean summer temperature that essentially controls the advance and retreat of glaciers. Precipitation plays a secondary part.

Some critics have further pointed out that the 'solar constant' is indeed rather constant. If it were not so, the continued existence of life on this planet over the past 3×10^9 years would not be possible. However, a number of recent palæoclimatic conferences and symposia have brought to light significant sources of radiative change, notably in the ultraviolet end of the solar spectrum. Furthermore, the much-maligned theory of Milankovitch, based on slight variations of this planet in its attitude and orbit, has been re-examined and found to play a certain part, notably in introducing long-term cycles, of 21,000, 40,000 and 92,000 years[1-3].

The consensus, in brief, at these recent conferences (New York Academy of Sciences, New York; Unesco–World Meteorological Organization, Rome; International Quaternary Association, Warsaw: all in 1961) suggests that climatic change is the product of a number of different mechanisms, varying considerably in orders of magnitude of both period and amplitude. The great long-range control is geological (relative position of poles, degree of mountain building, etc.); the middle-range control is astronomical (the celestial mechanics periodicity recognized by Milankovitch); and only the short-range controls are associated with solar radiation itself (correlation of ultra-violet-ozone production with sunspot variation, etc.).

The geological evidence of climate change in Africa was recognized almost a century ago. Around Cairo, for example, early workers such as Blanckenhorn noticed enormous gravel deposits in deeply scoured wadis where no water flows to-day. The same type of observations were made all across southern Europe and on other continents. It was easy, therefore, to conclude that during the last ice age a large increase in precipitation produced great snow and ice-fields, but that in the warmer latitudes of the Mediterranean and in Africa there was an age of tremendous rains. Indeed, the dry wadi beds have been followed all across the Sahara and old lake deposits have been recognized in East Africa, Australia, central Asia and in the Rocky Mountains of America.

Elementary Particles and Cosmic Rays

A. RAMAKRISHNAN, *University of Madras*

This informative volume surveys the theory of elementary particles and their interactions, with particular reference to cosmic rays and gives an integrated account of five major fields in modern physics: 1, Electrodynamics; 2, Meson physics; 3, Strange particles; 4, Cosmic rays; 5, The mathematical theory of cascades, with particular emphasis on the interconnection between them.

Contents : *Part I—ELEMENTARY PARTICLES.* Single particle wave functions and wave equations; Quantum electrodynamics; Formalism of quantum field theory; Pion physics; Non-perturbative approach to quantum field theory; Strange particles and their interactions; Weak interactions; Strong interactions and strange particles; Symmetries and strong interactions. *Part II—COSMIC RAYS.* Primary cosmic radiation; Geomagnetic effects; Interactions of cosmic rays with matter; Cascade processes; Origin of cosmic radiation; Appendices.

International Series of Monographs on Analytical Chemistry—Volume 5.

The Analytical Chemistry of Indium

A. I. BUSEV, *Professor of Analytical Chemistry, Moscow State University*

This outstanding volume covers all the most important methods of detection and quantitative determination of indium.

Advantages, shortcomings, and application limits for many methods are discussed, as well as their sensitivity, limiting ratios, accuracy, and reproducibility. Particularly reliable and tested methods are described in some detail.

Analytical chemists in scientific, plant and educational laboratories, and students attending special courses in analytical chemistry of rare and trace elements, will find this book invaluable.

Professor Busev is the author of five books and over 150 papers on the subject.

Chapter Headings include : The chemico-analytical character of indium; Methods based on the hydrolysis of indium compounds; Methods based on the precipitation of the Indium cation In^{3+} by inorganic anions; Methods based on the formation of compounds of indium, with carboxylic acids and aminopolycarboxylic acids and also with other organic reagents.

295 pages **84s. net**

Volatile Silicon Compounds

E. A. V. EBSWORTH, *Cambridge University*

A critical monograph describing the structural, physical and chemical properties of simple volatile silicon compounds, concentrating on the hydrides and their derivatives. Lucid discussions of previously unpublished research include structural information and nuclear magnetic resonance work on hydrogen and fluorine bound to silicon.

Chapter Headings : The S.I.H. bond; The Halides of Silicon; Compounds containing Silicon bound to elements of Groups IV, V and VI; Other Silicon compounds.

250 pages **Illustrated** **50s. net**

Isobaric Nuclei with the Mass Number A-73

YE. P. GRIGOR'EV, *Leningrad University*

This informative monograph devoted to atomic nuclei with the mass number A-73 brings together the material relating to these isotopes on the basis of a critical analysis and summarises the most reliable data on radiation energies, etc.

Contents Include : Decay schemes; Higher excited levels; Lifetimes of the levels of ^{73}Ge; Electron capture; Half-life of ^{73}Se; Decay scheme of ^{73}Se; Other isotopes with the mass number A-73.

Approx. 60 pages **18s. net**

Any volume sent on 30 days' approval, without obligation. *Please quote this journal when ordering*

ZEISS ELECTROLYTIC POLISHER

JENA—THE HOME OF ZEISS

A new development which enables Metallurgists to polish, electrolytically, metallurgical samples, to watch the process under brightfield incident light, with a binocular microscope giving a magnification of 210×, and to control the etching and select the required contrast. The instrument will accommodate samples 4 in. by 2 in. by 1¼ in thick.

This method opens up new possibilities in the study of surface phenomena, particularly in the case of soft metals with highly deformed surface layers, where important information may be obtained concerning the plastic behaviour and associated recrystallisation of the material.

This instrument is equally useful to the production engineer Whenever electrolytic polishing is used in mass production, it can be used to determine the work specifications.

Photomicrographic equipment can be used either in 35 mm or plate 6.5 × 9 cm.

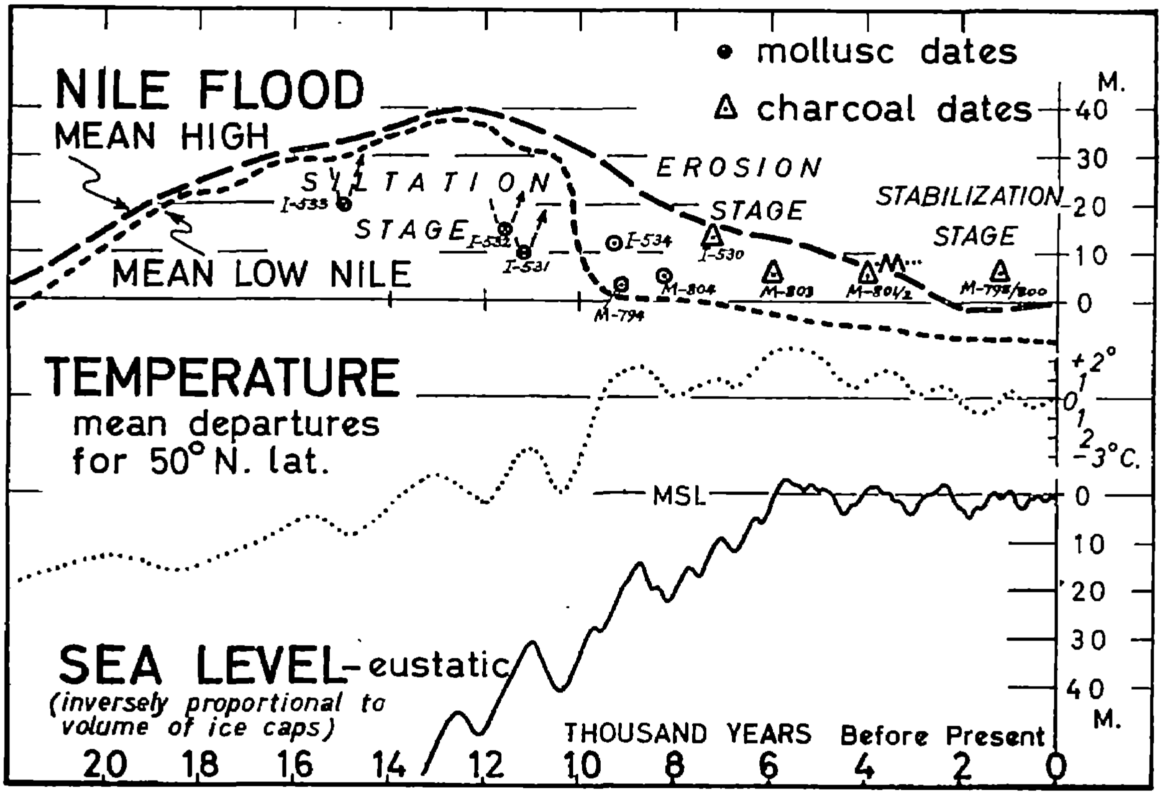

Fig. 1. Variations of middle Nile during past 20,000 years, according to recent radiocarbon dates. Three stages are shown: (*a*) *Siltation Stage* (note: shell samples *I*–531/3 represent temporary dissection of silts, but were immediately covered again—to 40 m depth); (*b*) ***Erosion stage*** (samples show progressive cutting down of the former silt fill of the valley, but were not afterwards covered by more than a few metres of sediment); *M* = the documented 'high Nile' of Amenemhat III, about 3,750 B.P. (*c*) ***Stabilization stage*** (the historical period; detailed oscillations, recorded by archæology and 'nilometers' have been omitted, for simplicity). Below, for comparison, are shown mean curves of temperature (for a typical western European latitude) based on palæobotanical data; and sea-level (eustatic), based on radiocarbon dating of old beach lines (refs. 1, 2). During the low-temperature period (maximum phase of last glaciation), equatorial rains were so reduced that the middle Nile was choked by silt (which is normally carried down to the Delta). Some cold winter rains reached the northern Sudan and produced gravels that interfinger the silts. During the high temperature and rapid glacier melting phase ('climate optimum' of Europe), c. 9,500–4,500 years B.P., sparse summer monsoonal rainfall commonly reached Egypt; to-day this rainfall boundary lies 1,000 km to the south

The evidence for great 'Pluvial Ages', which corresponded to the great Ice Ages, seemed overwhelming (see, for example, Büdel[4]).

Yet, recently, O. Davies (University of Ghana) remarked that the Pluvial Theory hung by a 'gossamer' thread. It has a certain weakness. The synchroneity of pluvial–glacial evidence in Africa was a pure assumption. It was well proved in temperate Europe, where geological relations with the ice margin were easy to work out, but the jump to central Africa was unsupported by intermediate, connective surveys.

On theoretical grounds, Albrecht Penck[5] objected to African pluvial–glacial synchroneity; he argued that the world atmospheric circulation system should remain basically the same, only to be reinforced or weakened from time to time in response to the heat energy that drives it. Thus climatic belts should migrate towards the equator during Ice Ages or vice versa during interglacials. Later[6] he pointed out that great lake developments in temperate latitudes during glacial periods would be the consequence of lower evaporation-rates. Flohn[7] has calculated that evaporation from the tropical oceans would be 20 per cent lower during glacial maxima.

It is apparent, therefore, that in the equatorial regions a lower evaporation-rate should be reflected by lower rainfall, particularly in the monsoonal belts. If Penck is right, the Nile should show a reduced flow during the ice ages and increased flow during interglacials. It should be noted that Emiliani's work[8] on the oxygen-18 isotope-palæotemperatures of tropical oceans shows that the present time is about 25 per cent less than the maximum of an interglacial–glacial cycle.

Radiocarbon Dates

A thick wedge of silts was built up to a height of 40 m above the rocky bed of the Nile in its middle sector during the Upper Pleistocene, thus reflecting a progressive diminution of the Nile discharge. At the present day, similar silts are carried right to the Delta. The middle part of this silt is dated by a bed of *Unio wilcocksi*, a large edible clam, associated with small inedible snails and other bivalves. The sample (Lab. No. *I*–533) is 14,950 ± 300 years B.P. Probably the oldest silts in the valley floor go back to 25,000 or 30,000 B.P.

The upper part of the silt is fixed by some small bivalves, *Corbicula artini* (Lab. No. *I*–532), with 11,650 ± 300 years B.P. Bivalves of this sort mark the middle and upper banks of the river seasonally submerged to-day. The permanently covered bed is better indicated by the Nile 'oyster', ***Etheria elliptica***, which colonizes rocky outcrops in the river bed. A sample from 10 m above present Nile flood-level at Wadi Halfa (*I*–531) is dated 11,200 ± 285 years B.P., and is thus comparable with the *Corbicula* beds (collected farther upstream near Akasha) at 20 m above present flood-level.

Sedimentation built up another 15 or 20 m above the *Corbicula* horizon during the next few hundred years, with a final peak-level about 10,000 years B.P. This must have been about the end of the last ice age desiccation of central Africa, because subsequent history of the middle Nile is one of almost constant cutting down of the river bed. Oscillations of the flow produced a series of terraces, sometimes marked by shell horizons.

One should note that while the maximum sedimentation-levels represent minimum fluvial discharge, in the subsequent dissection and terracing, the terrace deposits may, in contrast, represent abandoned flood-level deposits. A temporary low level (12 m above high Nile, south-east of Wadi Halfa) was marked by the little gastropods *Cleopatra bulimoides* (*I*–534), which dated 9,325 ± 250 years B.P. They were buried by a rising Nile which reached 20 m again. Another negative oscillation, to 13 m above high Nile, was marked by charcoal from a camp-fire site at Ukma (*I*–530), dated 7,300 ± 350 years B.P.

The climatic picture at this time (11,000–7,000 B.P.) in Egypt suggests a considerable incidence of rainfall[9], almost certainly in part summer monsoonal rains, for a rich and varied fauna migrated northwards and are faithfully recorded by artists of the Mesolithic and Neolithic cultures.

At this stage some other radiocarbon dates take up the record (see Fig. 1). Collected by Myers[10,11] from the region of Abka, 20 km south Wadi Halfa in an abandoned section of the Second Cataract, they show how the present level of the Nile was reached about 5,000 B.P.

The Dynastic Period and subsequent times, with man's predilection for building temples, further helps to fill in the story[12-14]. This is not the place for a analysis, but a preliminary study of the record suggests that there have been extended periods c relatively high and low Nile floods. Archæologicall dated 'high water marks' on Egyptian temples an associated Christian constructions near Wadi Half suggest that the last important high Nile periods wer about A.D. 500 and 800.

Conclusions

Comparison of this tentative curve for Nile oscillations with the eustatic curve (of world sea-leve variations), suggests that the 'minor oscillation are in phase, thus implying a common cause, though of course, with differing amplitudes. We feel the this common factor can only be solar radiation.

Much more work is needed, but it is suspected the the tropical lake beds of Africa will also prove to be i phase with solar radiation, while the temperat lake-levels will be out of phase. Further support offered to the concept of long-term climatic cyclicit with its potential for prediction.

OBITUARIES

Dr. E. W. R. Steacie, O.B.E., F.R.S.

Dr. E. W. R. Steacie, president of the National Research Council (Canada), died on August 28 in Ottawa after a brief illness at the age of sixty-one.

Dr. Steacie had been president of the National Research Council since 1952. He joined the Council in 1939, following a teaching and research career at McGill University. Well known as a physical chemist, he was at the time of his death serving in the three-year presidency of the International Council of Scientific Unions, the chief non-governmental organization for co-ordinating international activity in science.

Edgar William Richard Steacie was born on December 25, 1900, in Westmount, Quebec. He won the Gold Medal of the Westmount High School and the Westmount School Commissioners Scholarship. Enrolling at McGill University, he left to become a corporal in the Canadian Infantry during the First World War. He returned to McGill in 1920, and graduated in 1923 with the degree of B.Sc., with first-class honours in chemical engineering. During this period he won the British Association Medal for highest standing in the undergraduate course and a scholarship of the Imperial Order of the Daughters of the Empire. He obtained his M.Sc. in 1924 and his Ph.D. in 1926, both in physical chemistry from McGill. His postgraduate studies were aided by a Nation Research Council scholarship.

In 1923 he was appointed McGill demonstrator chemistry in McGill University. During 1926– he occupied the Sterry Hunt fellowship in chemistr becoming lecturer in chemistry in 1928 and assista professor of chemistry in 1930. He was on leave absence from McGill in 1934–35, when he did pos doctorate research at Frankfurt, Leipzig, and t University of London on a fellowship from t Royal Society of Canada. In 1937 he was appoint associate professor of chemistry at McGill.

Dr. Steacie joined the National Research Coun in 1939 as director of the Division of Chemistr He became vice-president (scientific) in 1950 an in April 1952, was elected president of the Council.

During the Second World War, Dr. Steacie play a large part in organizing Canadian chemistry f war purposes, especially in the fields of chemic warfare and the development of explosives. Duri 1944–46 he was deputy director, under Sir Jo Cockcroft, of the British–Canadian Atomic Ener Project in Montreal.

For his services during the War, he was appoint an Officer of the Order of the British Empire. He wa Fellow of the Royal Society of Canada and of t Royal Society of London. He was a Foreign Associa of the U.S. National Academy of Sciences of the United States, a Foreign Member of the Academy of Sciences of the U.S.S.R., an Honorary Member of the Polish Chemical Society and the Belgian Chemical Society, and an Honorary Fellow of the Chemical Society of London.

Among other honours, Dr. Steacie was awarded the Gold Medal of the Professional Institute of the Public Service of Canada (1949), the Palladium Medal of the Chemical Institute of Canada (1953), the Tory Medal of the Royal Society of Canada (1955), and eighteen honorary degrees.

One of Dr. Steacie's principal interests was the development of Canada's universities. He was at the time of his death serving as chairman of the Board of Governors of Carleton University, and chairman of the Advisory Committee for Science of the University of Ottawa.

Dr. Steacie's scientific work was in the fields of photochemistry, the kinetics of gas reactions, and free radical reactions, important as the basis of petroleum technology. The work consisted of fundamental research, without immediate application, but making outstanding contributions to basic knowledge. He had published more than two hundred scientific papers, and was the author of three books. One of his books, *Atomic and Free Radical Reactions*, is regarded as the standard text on that subject.

Besides serving as president of the National Research Council, Dr. Steacie was a member of the Defence Research Board and the Atomic Energy Control Board, and a director of Canadian Patents and Development Limited and the Canadian Standards Association.

Dr. J. W. T. Walsh, O.B.E.

By the death of Dr. J. W. T. Walsh on July 17, at the age of seventy, the world has lost one of its leading figures in the field of lighting and photometry. Dr. Walsh was a man of very wide interests and had long been held, both nationally and internationally, in the highest regard and esteem.

Educated at Hampton Grammar School and Merton College, Oxford, he went to the National Physical Laboratory to work under Sir Clifford Paterson (then Mr. C. C. Paterson), and when the latter left the Laboratory in 1919, Dr. Walsh remained to take charge of the work on photometry, until his retirement in 1951. During this period, he was able to exercise, through his position at the Laboratory, a considerable influence on the advances made in photometry, particularly those concerned with the change from visual to physical methods of measurement and with the adoption internationally of a black body radiator as the primary standard of light in place of sets of filament lamps.

His versatile gifts were used to the full on many other aspects of his subject. He served on numerous committees, a specially important one being the Home Office Committee which drew up the first regulations for standards of lighting in factories. He became a founder member of the British Standards Institution Illumination Industry Standards Committee in 1927 and served as its chairman during 1945–55; the subjects in which he was particularly interested were street lighting and nomenclature. He also wrote a number of books, notably his text-book on *Photometry*, the latest of three editions having been published in 1958. In addition, he was the author of numerous papers.

In 1929 he was elected to membership of the Institution of Electrical Engineers, after being an associate member from 1918, and was awarded the Kelvin and Ayrton premiums.

For many years he played a very active part in the Illuminating Engineering Society and he achieved the unique distinction of being elected its president on two separate occasions, in 1929 and 1947.

Dr. Walsh's interest in illumination extended also to the work of the National Illumination Committee, to which he was appointed as the representative of the National Physical Laboratory as far back as 1919. He served as chairman during 1945–55. This work brought him into close touch with the parent International Commission on Illumination, the general secretary of which was provided by the National Physical Laboratory for the period between the ends of the two World Wars. Dr. Walsh himself was the first to hold office in this period (during 1921–28) and was honorary secretary during 1928–31. He attended every meeting of the Commission up to the most recent one in 1959. Throughout this time he steadily built up a reputation as one of the Commission's leading figures and in 1948 was appointed one of its vice-presidents. Later, in 1955, full recognition was given to him by his appointment as president and he duly presided over the next meeting at Brussels in 1959. It is understood that he had recently completed a history of the Commission, and the publication of this will be awaited with much interest.

Recognition of his work was acknowledged in 1951 by his appointment as an Officer of the Order of the British Empire.

During his early time at the National Physical Laboratory Dr. Walsh took a considerable interest in its social activities, but later much of his private life was devoted to youth work, both on behalf of organizations such as the Boy Scouts and in numerous individual cases. He was also interested in education and served on a number of local bodies. He gave a start in life to very many less fortunate than himself.

Although a bachelor with few family connexions, he was by his wide and humane interests a man with innumerable friends in many countries and his passing will be universally mourned.

J. S. Preston
L. H. McDermott

Prof. S. Mangham

Sydney Mangham, who died on July 30 at the age of 76, was the first professor of botany in what was then the University College of Southampton. Sutherland, and before him Cavers, had been professors of biology; but in 1920 the department was divided. Sherriffs was made head of the department of zoology, and Mangham was appointed to the new chair of botany. For the first seven years of his professorship Mangham's staff consisted of one lecturer, Miss F. M. Loader (who remained with him during the whole of his tenure), a temporary and ever-changing student assistant, and a lab-boy; and Mangham taught virtually all branches of botany at all levels, including a course for gardeners. Had he been a man of strong research interests, the task would have been intolerable; but his early interests in analytical techniques and in translocation rapidly succumbed to his genuine love of teaching. Dissatisfied with existing introductory text-books he wrote *A First Biology* and *A Second Biology* with

Sherriffs; then *A Text-Book of Biology* with Hockley; and, lastly, the still-popular *Earth's Green Mantle*—the title of which was borrowed by Tansley, with Mangham's permission, for his own *Britain's Green Mantle*. Mangham was a first-class draughtsman, and his elegant diagrams contributed much to the success of his books.

He enjoyed field excursions, and at 65 could still out-walk many of his students; he knew his plants and was not alone in finding nomenclatural changes exasperating; and he loved—and was justly proud of—his garden. After his retirement in 1951, and after an Australian tour, he returned to the now University of Southampton as curator of grounds, a post which gave him great pleasure and which he filled with distinction until, on the death of his wife in 1957, he moved from the town.

Few of us to-day would be willing to do as much as Mangham did with so little assistance, and to devote thirty years to keeping a small Department going at the cost of our own scientific work and advancement. But his faith in the importance of his subject and in the future of his Department was proof against all inadequacies of staff, finance and space, and he laboured selflessly to ease the path of his successor. The building which he and an engineering colleague personally designed—without the help of an architect—is still in use to-day; and his memory is honoured in the Department, the continued existence of which he made possible. W. T. WILLIAMS

NEWS and VIEWS

Botany at Glasgow : Prof. J. Walton

PROF. JOHN WALTON, regius professor of botany in the University of Glasgow since 1930, who retired on September 30, was educated at Daniel Stewart's College, Edinburgh, and St. John's College, Cambridge (where he was awarded the Hutchinson Research Studentship). He went as botanist on the First Oxford Expedition to Spitsbergen in 1921 and on his return to Cambridge was appointed junior demonstrator. His palæobotanical researches were there begun under the late Sir Albert Seward. From 1923 he held the post of lecturer in botany in the University of Manchester until his appointment to the Glasgow chair. Part of his early work was concerned with new techniques of investigating fossil plants. In 1923 he published an account of his balsam transfer method, whereby plant compressions could be transferred to a transparent base to facilitate microscopic examination. His well-known 'peel' technique, a rapid and easy method of obtaining thin sections of petrified fossil plants, was published in 1928. Another of his early publications was concerned with the factors affecting the form of fossil plants. Most of his work, however, consisted of investigations of Palæozoic plants, particularly those of the Welsh and Scottish Lower Carboniferous. Over the years our knowledge of these strata, which are of special importance in fossil botany, has been greatly increased by Walton and his students. However, the foregoing are only indications, for his interests in both fossil and living plants extended over a wide field.

Among his many distinctions, Walton was awarded the degrees of D.Sc. (Manchester), Sc.D. (Cantab.) and the honorary degrees of Ll.D. of McMaster University and D.-ès.-Sc. of the University of Montpellier. In 1931 he was elected a Fellow of the Royal Society of Edinburgh, on the Council of which he served for some years. During 1949–53 he was a Forestry Commissioner and during the same period he served as a member of the Scottish Committee of the Nature Conservancy. He was elected president of the Botanical Society of Edinburgh, 1962. Among his many other social and scholarly interests and activities, it was perhaps no less than appropriate that he, the son of a distinguished artist, should have served as honorary curator of the very important art collections belonging to the University of Glasgow.

Dr. P. W. Brian, F.R.S.

DR. PERCY WRAGG BRIAN, who succeeds Prof. Walton in the regius chair of botany at Glasgow, has for the past twenty-six years been on the scientific staff of Imperial Chemical Industries, Ltd., from 1936 until 1946 as mycologist at the Jealott's Hill Research Station, Bracknell, Berks., since then as head of the Department of Microbiology, Akers Research Laboratories, Welwyn, Herts. Dr. Brian was educated at King Edward's School, Birminghan, and at King's College, Cambridge. He held the Frank Smart studentship in botany at Cambridge in 1933–34 and spent the next two years as assistant plant pathologist at the Long Ashton Research Station. Dr. Brian's versatility is well known. His personal research work has included notable contributions to both agriculture and industrial microbiology, while he has inspired a team of mycologists, microbiologists and chemists to break much new ground in the field of biologically active substances produced by fungi. Among the numerous antibiotics first characterized by Dr. Brian, mention may be made of griseofulvin, which in addition to its horticultural use as a systemic fungicide has during the past few years become notorious for its use in the oral therapy of ringworm of man and animals. Another notable series of his researches has been concerned with the gibberellins. Dr. Brian gave the Cantor lectures to the Royal Society of Arts in 1953, was elected to the Royal Society in 1958, served the British Mycological Society as president in 1960, and in 1961–62 was similarly honoured by the Association of Applied Biologists. He will bring this wide experience of applied microbiology to the University of Glasgow when next year he takes up his new post.

National Coal Board Research and Development Organization

WITH effect from October 1, the National Coal Board made changes in the departmental responsibilities for research and development. That directly concerned with the production, working and preparation of coal became the responsibility of the production member of the Board, Mr. H. E. Collins, and that concerned with coal processing and combustion became the responsibility of the scientific member of the Board, Mr. A. H. A. Wynn. The main effect of these changes is that the Mining Research Establishment at Isleworth comes under the Production Department. Dr. W. Idris Jones has been appointed director general of research and development (Coal Processing and Combustion) and will be head of the Scientific Department. He will continue to control the Coal Research Establishment at Stoke Orchard, Cheltenham, and extramural research Mr. B. L. Metcalf has been appointed deputy director general of research and development (mining). He will co-ordinate all research and development in the mining field, and will control the Mining Research Establishment as well as the Central Engineering Establishment at Bretby.

Dr. W. Idris Jones, C.B.E.

DR. IDRIS JONES graduated with honours in chemistry at University College, Aberystwyth, in 1921. He was Rhondda and Frank Smart research student of Gonville and Caius College, Cambridge, during 1923–25. On leaving Cambridge, Dr Idris Jones joined the research staff of Synthetic Ammonia and Nitrates, Ltd. (now a subsidiary of Imperial Chemical Industries), and was later appointed a group manager in the Oil Division, where he was concerned with the development of the coal hydrogenation process. In 1933 he was appointed director of research, Powell Duffryn Co , a position which he held until November 1946. Dr. Idris Jones, besides being Fellow or member of many learned societies and institutes, is president, chairman of Council and of the Research Committee of the British Coal Utilization Research Association, and chairman of the British Standards Institution Solid Fuel Industries Standards Committee. He was awarded the C.B.E. in June 1954.

Mr. B. L. Metcalf

BERNARD LESLIE METCALF studied at the University of Glasgow and spent a year on postgraduate work in the mechanical engineering laboratories of the Royal Technical College, Glasgow. In 1923 he began a college apprenticeship course with Metropolitan-Vickers at Trafford Park, Manchester. Later he spent a year at some of the first power stations to be built under Lenin's electrification scheme in the U.S.S.R. Afterwards he was stationed in Japan for the Metrovick Export Co. for five years. Back at Trafford Park, Mr. Metcalf joined the Mining Department, later being appointed engineer-in-charge of that Department, but leaving in 1939 to become chief electrical engineer of Powell Duffryn Co. In 1945 he joined the Brush Electrical Engineering Co. in Loughborough as technical director. He became director of engineering at the National Coal Board in 1948.

Waterston and the Kinetic Theory of Molecules

DR. W. P D. WIGHTMAN, reader in history and philosophy of science in the University of Aberdeen, writes as follows: "In his illuminating article [*Nature*, 195, 744; 1962] on Maxwell's contributions to kinetic theory, Prof. C. A. Coulson states that 'up to this date it had apparently been assumed, by Clausius and others, that as these minute particles flew around in all directions, they maintained always the same uniform speed'. Though most writers (including Prof. Coulson) now give J. J. Waterston the credit for his pioneering memoir on this subject, it does not seem to be generally known that he clearly recognized the essentially statistical nature of the problem. 'Considered separately', he wrote, 'they (*sc.* the molecules) are for ever continually changing the velocity and direction of their individual motions. . . they run rapidly in their zig-zag conflict through every possible mode of concurrence . . .' ('On the Physics of Media that are Composed of Free and Perfectly Elastic Molecules in a State of Motion' (1845). *Collected Scientific Papers*, edited by J. S. Haldane, p. 216. Edinburgh, 1928). In such mathematical elaboration as he attempted he consistently used the terms 'mean velocity' or 'mean square velocity'."

Re-vitalizing School Mathematics

SCHOOL mathematical syllabuses have remained virtually unchanged for many years and have not adequately reflected the great strides that have been made in mathematical theory and practice during the present century. Many countries are now realizing the necessity of re-vitalizing their syllabuses; for example, the United States and the four Scandinavian countries. So far, such work in Britain has been confined to the efforts of a few individual schools, and the School Mathematics Project has been formed to carry such efforts a stage further. It consists of a group of schools containing experienced and vigorous authors and a good cross-section of types of pupil in sufficient numbers to make extensive experiment with a special syllabus feasible and worth while. The aim of the reformed syllabus is not simply the production of more and better professional mathematicians, but is mainly to provide the boy or girl whose mathematical education finishes at 'O' or 'A' level with some insight into the nature of mathematics, into what mathematicians do and into the use of mathematics in the modern world. Inseparable from the problem of what to teach is the problem of how to teach, and research is essential into the ways in which modern mathematics can best be taught. The Project is maintaining the closest contact with the Nuffield Foundation's projects for the reform of the 'O' level science subjects. The Project is based on the University of Southampton and is directed by Prof. B. Thwaites. The University has already appointed in the Department of Mathematics Dr. A. G. Howson, who has special responsibilities towards the Project; it has approved also the establishment of a readership.

MR. M. G. HUGHES, headmaster of Dynevor School, Swansea, on the invitation of the Central Advisory Council for Education (Wales), has prepared a useful report, *Modernising School Mathematics: a Review of New Trends in Mathematical Education at the Secondary Stage*, now sponsored for publication by the Mathematical Association (Pp. 43. London: G. Bell and Sons, Ltd., 1962. 2*s*. 6*d*. net). Mr. Hughes describes what is being done to bring school mathematics up to date, with reasonable brevity in 40 pages, by avoiding unimportant syllabus details. He deals concisely with the case for modernization, gives an account of progress in the United States and of the radical suggestions made at the Royaumont Seminar of the Organization for European Co-operation and Development. The last three sections deal with work in the United Kingdom, such as new diplomas instituted by the Mathematical Association, the pilot scheme under Prof. Thwaites in which the University of Southampton is to co-operate with Charterhouse, Marlborough, Sherborne and Winchester in preparing new syllabuses and producing the relevant text-books, and the proposal by a committee headed by Sir William Hodge that a Federal Council of Mathematics should be set up to co-ordinate all British activities in this field. Teachers of mathematics should read this slim book; they will learn that the difficult and pressing problem is not being neglected, and they will be shown ways in which they may make a contribution to its solution.

European Society for the Study of the Toxicity of Drugs

Scientists employed by the major European pharmaceutical companies who have as their responsibility the safety of a drug met in Zurich on September 20 to discuss their problems. It was decided that every effort should be made to encourage research into methodology and the exchange of information in this field. Towards this end a European Society for the Study of the Toxicity of Drugs was formed, and the following committee was appointed to establish the Society and arrange its meetings: Dr. D. G. Davey, Imperial Chemical Industries, Ltd., Pharmaceuticals Division, England (*chairman*); Dr. P. Koetschet, Rhône-Poulenc, Paris, France; Dr. G. A. Overbeek, N.V. Organon, Oss, Holland; Dr. J. Scholz, Farbwerke Hoechst AG, Frankfurt (M), Germany; Dr. M. Tausk, N.V. Organon, Oss, Holland; Dr. J. Tripod, Ciba A.G., Basle, Switzerland (*secretary*). Membership of this Society is open to all scientists interested, whether employed in industry, universities, Government or international organizations. Further information concerning the organization and application forms for membership can be obtained from the secretary.

The Hampshire South Downs

An area of the Hampshire South Downs, about 151 square miles in extent, is the subject of an order made by the National Parks Commission for protection. The area stretches from the outskirts of Winchester to the Hampshire–Sussex border at a distance of about ten miles inland from the south coast, and includes Petersfield and Selborne. It is a natural extension of the chalk uplands of the South Downs as far west as Old Winchester Hill and the Meon Valley. Further westwards it merges gradually into rolling farmland. In the northern part of the area beechwoods cover the scarp from above Petersfield to Selborne Hangar. The order, which is made under the National Parks and Access to the Countryside Act, 1949, designates the Hampshire downland as an "Area of Outstanding Natural Beauty" and not as a National Park. The responsibility for preserving and enhancing the natural beauty of the landscape rests with the local planning authority, Hampshire County Council. Government grants can be made at the rate of 75 per cent towards the cost of tree planting and preservation, and removing disfigurements. Grants are also available towards expenditure incurred in making agreements or orders for public access to open country and in appointing wardens.

Wild and Domestic Animals

In the August issue of *Man* there is a note by E. S. Higgs on a metrical analysis of some prehistoric bovine and caprini bones from the cave of Haua Fteah in Cyrenaica. Mr. Higgs has been assisting at the excavation of this large site and dealing with the extensive fauna that has been unearthed. The cultures found date from Levallois-Mousterian, Capsian and Oranian times, and pass up into the Neolithic and later periods. It has been possible, therefore, to study the effect of domestication on the bony structure of wild animals, accepting that domestication results in a decrease in size of the animals concerned, and that with domestication a larger number of young animals will be killed for food than would be by the people of a hunting culture. The results are of much interest and the information and charts which appear in the paper are of importance. There is no evidence at Haua Fteah of 'on the spot' domestication of sheep and cattle from indigenous wild stocks, as the domestic animals here seem to have been introduced from elsewhere. The date for the existence of domestic sheep in North Africa is pushed back to about 4800 B.C.

Announcements

Air Commodore D. D. Hatfield has been appointed director of air armament (research and development), Ministry of Aviation, with effect from December 3, 1962.

Dr. Harvey I. Scudder, assistant to the Chief of the Division of Research Grants, has been appointed chief of the Research Training Branch, Division of General Medical Sciences, National Institutes of Health. In this position, Dr. Scudder will supervise the operations of the Research Training Branch providing research fellowships, career awards, career development awards and training grants in the general scientific disciplines basic to medicine and health.

Mr. Olav R. Kåsa, project manager of the Organization for European Co-operation and Development Halden Reactor Project and deputy director of the Institutt for Atomenergi, Kjeller, Norway, has returned to Kjeller, where he has now become director of reactor development. Mr. Emil Jansen, who was previously director of reactor development, has been appointed project manager at Halden, and Mr. Henrik Ager-Hanssen, formerly head of research of the Halden Project, has been appointed deputy project manager.

The 1962 Arthur Stanley Eddington Memorial Lecture, entitled "On Having a Mind", will be given by Prof. W. C. Kneale at the Arts' School Lecture Theatre, Cambridge, on November 9. Further information can be obtained from the Arthur Stanley Eddington Memorial Trust, King's Court, 48 Broadway, London, S.W.1.

An international conference on "The Operating Experience and Future Development of Power Reactors and Radioisotopes", sponsored by the Canadian Nuclear Association, will be held in Montreal during May 27–29, 1963. Further information can be obtained from the General Manager, Canadian Nuclear Association, 19 Richmond Street West, Toronto 1.

A symposium on "High Pressure Measurement", sponsored by the Research Committee on Mechanical Pressure Elements of the American Society of Mechanical Engineers as part of the winter annual meeting of the Society, will be held in New York during November 28–30. Further information can be obtained from the American Society of Mechanical Engineers, 345 East Forty-Seventh Street, New York 17, N.Y.

SCIENTIFIC RESEARCH FOR INDUSTRY IN BRITAIN

*RESEARCH for Industry, 1961**, follows the pattern of recent reports. The bulk of the report—86 pages out of 134—lists the 49 research associations serving particular sections of industry and the three organizations serving industry as a whole, namely, the Commonwealth Mycological Institute, the National Institute of Industrial Psychology and Aslib. For each is given the present addresses of the laboratories and offices, the Chairman of Council and Director of Research and the total income, with a brief indication of the scope of the present work and a list of publications in 1961. This list is preceded by a short review of the principal achievements of eleven research associations the grants of which came up for review in 1961. The retiring chairman of the Industrial Grants Committee, Sir Walter Drummond, contributes some reflexions on research associations in which he stresses the saving in scientific manpower effected by co-operation in this way, and Dr. W. F. Watson writes on research associations and the consumer, indicating some of the benefits which accrue directly to the consumer from the work of the associations.

The major interest of the report as a whole lies in the report of the Industrial Grants Committee itself, which this year provides the comprehensive review of the research associations which the Minister for Science last November said he had asked the then new chairman of the Council for Scientific and Industrial Research, Sir Harold Roxbee Cox, to institute. An accompanying statement indicates that the Research Council has also reviewed the situation in the light of recent discussions and reports and that the analysis and statement of policy contained in this report has its support and also that of the Minister for Science. This analysis and statement is discussed elsewhere (see p. 97 of this issue). In what follows here some of the achievements of the association are selected for note.

The most important single contribution of the British Baking Industries Research Association in recent years has been the devising of the Chorleywood bread process, which cuts the total time required to process bread from more than 4 to less than 2 hours and is estimated to offer bakers savings of about 2*s*. 6*d*. per sack of 280 lb. of flour. Fundamental research includes an investigation of the factors which underlie the elastic properties of wheat proteins, a detailed investigation of the liquids present in flour derived from wheats of different varieties and a study of the swelling and shrinking of starch during and after baking. During the year the Cotton, Silk and Man-made Fibres Research Association made available to members nine new types of equipment based on a previous research, of which the 'separator for hard wastes' is estimated to offer savings of £200,000 a year and the Shirley Pressure-Point System of dust extraction from cards leads to a much clearer atmosphere in mills, and has been recommended to the industry by the Joint Advisory Committee of the Cotton Industry. Work on the application of 'fluid beds' to textile processing continues, and Shirlastain *E* has been developed for the rapid identification of synthetic fibres: in combination with Shirlastain *A*, *D* and *A–D* it permits rapid and conclusive identification of any mixture of fibres. At least fourteen new instruments have been developed during the past five years.

The British Electrical and Allied Industries Research Association reports important scientific advances in explaining the variation of intrinsic strength of thermo-plastics with temperature, and in diagnosing the mechanism of action of traces of moisture in impregnated cellular materials and evaluating its effect on electric strength. A survey of technical detail associated with all lighting on overhead lines in Great Britain during 1956–60 promises to offer a reduction of 10 per cent in the incidence of circuit interruptions due to lightning. The British Food Manufacturing Industries Research Association has studied the public health aspects of the marketing of meat products in partly vacuumized flexible film pouches and has designed an instrument for studying the somewhat complex rheological properties of chocolate and devised a novel method of evaluating the flow properties of chocolate. An instrument developed in collaboration with the National Institute for Research in Dairying for measuring the 'spreadability' of margarine and cooking fats is now in commercial production and is also of interest in the fields of explosives, cosmetics and welding fluxes.

The main effort of the File Research Council has been devoted to the development of new methods and machinery to increase the productivity of member firms, but knowledge gained from investigation of the factors affecting file quality has been used to ensure that new machinery will also give products of uniformly high quality.

During the past five years, the selection of suitable varieties has been carried out by the Fruit and Vegetable Canning and Quick Freezing Research Association, and a selection based on chemical composition, which has had a spectacular success with broad beans for canning, has been adopted for the selection of other materials, notably Bartlett pears and, more recently, rhubarb. A survey has also been made of the quality of frozen peas reaching the consumer, and a series of studies with the antibiotic nisin has shown that it has no effect on the heat resistance of the spores of certain spoilage bacteria in canned foods but that it blocks either the germination or the outgrowth of the spores.

At the British Internal Combustion Engine Research Association Laboratory an engine designed originally for atmospheric charging with a similar overload rating of 97·5 lb./sq. in. bmep has been turbocharged to carry three times that load without excessive stress in any part. Prolonged testing has shown that the Association's Mark I fuel injection system merits serious consideration for engines of the future. The British Non-Ferrous Metals Research Association has devoted considerable effort in the past few years to measuring the emission of smoke and fume from stacks serving a wide variety of processes

* Department of Scientific and Industrial Research. *Research for Industry 1961: A Report on Work done by Industrial Research Associations in the Government Scheme*. Pp. iv + 140 + 12 plates. (London: H.M.S.O., 1962.) 10*s*. net.

in the copper and copper alloy and aluminium industries, and the efficiency of different types of cleaning plant. Corrosion studies continued to occupy a large place in the Association's programme, and, besides development of a thermo-electric gauge for the non-destructive measurement of the thickness of metal coatings, creep-resisting alloys have been developed, including thorium alloys for possible nuclear fuels, titanium alloys for gas-turbine compressor blocking and zirconium alloys for constructional purposes in nuclear plant. Potentiometer studies by the Research Association of British Paint, Colour and Varnish Manufacturers have advanced knowledge of the influence of many anti-corrosive pigments on the electro-chemistry of corrosion processes, and, together with radio-chemical and autoradiographic techniques, have gone far to show how red lead pigment in paint behaves on steel and non-ferrous metals. Studies on materials for the protection of metal-sprayed steel have indicated the value of etch primer pre-treatments and of paint media which do not react with the sprayed metals, and have influenced the choice of treatments designed for the Forth and Tamar road bridges. The development of testing methods to indicate the firing propensity of the class of organic pigments known as toners when treated with resinous materials to enhance colour quality and investigations of the effect of various kinds of resin used have led to a marked decrease of such fires.

The Production Engineering Research Association has developed an improved design of reamer which is estimated to increase production-rates by 2–5 times in most industrial applications and the reamer life 3–8 times. New approaches are being made to the design of structures, and the principles evolved are being increasingly applied by machine-tool makers in the design and manufacture of new machines, while a detailed metallographic study of the mechanism of shear during hole-punching operations has resulted in a new technique for producing precision punched holes in sheet or strip materials, known as finish piercing. A new model of automatic spring-coiling machine being developed by the Spring Manufacturers' Research Association is expected to capture a large part of the export market. The results of investigations of the effect of non-metallic coatings on the corrosion–fatigue strength of springs which have shown that several resinous and plastic coatings possess good adhesion, abrasion resistance and mechanical strength, as well as withstanding corrosion–fatigue conditions for more than 50×10^6 stress reversals are being applied in the industry to protect finished springs against corrosion.

THE MEDICAL RESEARCH COUNCIL

BESIDES accounts of the work of its own research units and that of institutions which it assists with finance, the annual report of the Medical Research Council is of interest to all men of science for the lucidity of a series of articles which have been selected to illustrate some aspects of the Council's work*. Among them are the physiological exploration of physical symptoms of mental and cerebral illness; mental disorders in old age; replacement therapy in hæmophilia and Christmas disease; trachoma and inclusion blennorrhœa; the early lesion of dental caries; the bacterial cell wall and the anthropological significance of blood groups.

Of outstanding value, however, is an important article describing the modern role of a research council in encouraging medical and biological research.

It is now fifty years since, with the creation of the former Medical Research Committee, Great Britain took the lead in setting up central organizations for research. During this period, society, in common with those of other developed countries, has changed profoundly. Fifty years ago appreciation of the part that research would come to play in the machinery of Government was confined to a few far-sighted men. Now it is taken for granted, and the question of how most effectively to organize support for research and development has become a matter of continuing concern to all modern Governments.

In the course of its development a central organization for research passes through a series of stages.

At the outset it is conceived of as a means of satisfying certain special needs which cannot be or are not being met by existing agencies for research—universities on one hand and the practising profession or industry on the other.

It is soon found, however, that these *ad hoc* requirements cannot always be met on the basis of existing knowledge, nor can reliance be placed on the chance that the interests of others will incidentally produce what is required. The second stage is then entered, when such organizations are driven to employ their own staff and find themselves increasingly involved in 'basic' research to fill gaps in knowledge that they have identified. In Great Britain, this stage was reached before the end of the First World War.

The next stage comes with the recognition that it is impossible for any organization to foresee its needs for more than a few steps ahead; that it is no more than enlightened self-interest to support any research that promises additions to knowledge even though its practical utilization cannot immediately be foreseen. In the 1930's, for example, it was impossible to foresee the atom bomb and, consequently, the hazards to health that might follow its use. Had not the Medical Research Council supported as subjects for study, in their own right, research into the effects of ionizing radiations on cells and on the production of mutations, they would not have been in a position, twenty-five years later, to give an assessment to the Government of the effects of fall-out or the hazards of such radiation. Again, looking to the future, the problem of 'population pressures' is looming ahead. Necessarily such a problem cannot be approached directly, and only partially by retrospective observation on human populations. It is evident, however, that if informed judgements are to be made, every fragment of knowledge from ecology, ethology, nutrition and genetics may be required.

The Medical Research Council conceives its function as: to watch over the whole fields of medical and related biological research so as to foresee, to the best of its ability, the needs and opportunities; to give support to any promising research in these fields irrespective of the agent concerned; to work in partnership with the universities and professions on one hand and the various Government departments on the other, so that new knowledge may be made available as the need arises.

---

* Committee of Privy Council for Medical Research. Report of the Medical Research Council for the year 1960–1961. Pp. viii+372. (Cmnd. 1783.) (London: H.M.S.O. 1962.) 21s. net.

It is according to this concept that the Council has devised its organization and formulated principles of working. These developments in the concept of the function of a central research organization are set out for two reasons. The first is that it is not yet fully realized that, nowadays, such organizations cannot remain pre-occupied with the institutions and staff for which they are directly responsible, but must pay attention to the development of knowledge as a whole in the field with which they are concerned. The second is that, when viewed in this larger perspective, many of the detailed problems of management disappear.

At the level of management the task of a research council is to reconcile two apparently conflicting requirements. On one hand, it has to try to ensure that the new knowledge required by society through Government is forthcoming and to this end has to distribute its support of research according to its assessment of present and future needs. On the other hand, it has so to devise its conditions of support as to preserve to individual workers that intellectual initiative without which creative work cannot develop. The problem for a research organization is thus to reconcile the implementation of a balanced and comprehensive research policy at the national level with the need for intellectual freedom at the level of the individual or the research team.

The solution of this dilemma is largely a matter of the scale of operation. If resources are restricted, or one thinks only in terms of individual institutions or particular organizations, the dilemma is real, and, in order to discharge its social obligations, a research organization may then be forced to have recourse to control and direction, even at the risk of inhibiting its workers in the creative thought and initiative on which its efficiency ultimately depends. But if the scale of operation is adequate the difficulty need not arise; for if support has been spread widely and with foresight, and if the central organization commands the confidence of scientists in general, then the relevant spontaneous interest can practically always be found. In other words, the solution of the dilemma lies in drawing a distinction between direction of research policy and directing individuals. It is of the essence of policy to have an object; but in relation to creative work the path to that object lies not through prescription to individuals, but through the informed selection of projects to be supported.

The question of what is adequate scale of operation for a central research organization with comprehensive social obligations in its particular field is, therefore, of critical importance. To-day the answer can no longer be in doubt. The demand for new knowledge is such that nothing less than the national scale will suffice, for it is only on this scale that the requisite variety of research work, interests and institutions can be found to allow the necessary freedom of initiative in policy.

There are only two qualitatively different types of scientific investigation: that which is directed to increasing understanding of naturally occurring phenomena—research—and that which aims at bringing knowledge so gained to the solution of human needs—applied research or development. Even these are little more than abstractions at either extreme of the range. Between them lie every shade and combination of activity, and it is this that makes organization in science possible. No research worker is entirely divorced in interest from his fellows or indifferent either to the use that can be made of his work or to its theoretical implications. All range, to some extent, about the centre-point of their interests, provided that they are not prevented by segregation from habitual contact with workers whose interests are contiguous. It is a major task of organization to promote such interplay. Blood transfusion would be hamstrung if separated from relevant investigations in genetics or immunopathology. Research in endocrinology would be grossly handicapped but for the experience available in clinical practice. Laboratory and practical work in nutrition mutually interact. The interdependence of chemistry, biochemistry, chemical pathology and the study of human metabolic diseases is evident. There is a regrouping of disciplines, a prominent feature of which is the disappearance of the previous barriers between the laboratory and practice. It would be undesirable, on either theoretical or practical grounds, to do anything that tended to separate research aimed at the applications of knowledge from the investigation of natural phenomena out of which this knowledge grows.

The remainder of this valuable survey into the role of a research council examines the Medical Research Council's relationship to Government. Its significance as a court of appeal in various aspects of medicine is but one tribute to its well-recognized independence.

THE ELECTRICAL RESEARCH ASSOCIATION 1961

It is significant that the opening paragraph of the report for 1961 of the Electrical Research Association* is headed "Electronics". The paragraph records a decision of the Council to expand the activities of the Association in the electronics field.

When the Association was formed in 1920 the part played by electronics in the electrical industry had scarcely become appreciable. Developments were just beginning whereby telecommunication in all its forms was to be revolutionized and, at a later stage, profound changes were to be effected in many branches of heavy electrical engineering.

The research effort of the Association has been directed primarily towards problems in the heavy current field, but there has been a natural development of interest and activity in the many incidental applications of electronics. It is estimated that about 12 per cent of the Association's present research activities is of direct interest to the electronics branch of the industry and a further 6 per cent of indirect interest. Having regard to the central position which electronics is assuming in the electrical industry as a whole, it is now considered that the research programmes devoted to electronics and related subjects should be expanded until they reach half the total. The Council of the Association therefore proposes to examine the probable response from industry to the development of a programme much more biased towards the electronics side.

---

* Electrical Research Association. 41st Annual Report for the year ended 31st December, 1961. Pp. 104. (E.R.A./T. 476.) (Leatherhead Electrical Research Association, 1962.)

Results obtained during the past year are summarized in the Director's Report on research work under six divisional headings. Division 1, that of insulating materials, reports the continuation of the Association's work on solid and on liquid dielectrics both in the laboratories at Leatherhead and in the University Laboratories at Liverpool, Birmingham and London. The Leatherhead Laboratories are now equipped to make dielectric measurements in inert atmospheres at pressures up to 20 atmospheres and temperatures to 500° C. Work on the high-permittivity 'Skanavi' materials has shown these substances to possess two phases, at least one of which is a ferro-electric with an extremely low coercive force.

In an attempt to locate minute leakage paths through paper capacitor tissue a new technique has been devised in which the leakage current electrolyses a thin evaporated aluminium electrode. Small areas of exceptional current density can be detected in this way. The deposition of very thin films of dielectric polymers from the monomer vapour under the action of a high-frequency discharge has been successfully effected. In the field of theoretical physics work on semi-conductors has produced an interesting and potentially important result, namely, that in semiconductors with very low mobility the so-called 'band model' becomes invalid. It has been shown that the band model is valid for mobilities down to the order of $1\ \text{cm}^2\ \text{sec}^{-1}\ \text{V}^{-1}$.

Under Division 2, "Power Plant", it is reported that the new laboratory for the investigation of the creep behaviour of steels is now in full operation. The programme of work which is proceeding includes long-time rupture tests on pipes and superheater tubes, creep and rupture properties of castings for turbine casings and of forgings for turbine rotors, also of steels for turbine blades. The experimental work on the properties of steam is now being extended along the 400° C and 600° C isotherms to a pressure of $9,000\ \text{lb./in.}^2$, the results available up to $5,800\ \text{lb/in.}^2$ and 750° C having been reported during the year.

Of particular interest is a group of experiments designed to obtain data required in the investigation of some of the proposed new methods of energy conversion, namely, thermonuclear fusion, magnetohydrodynamic generation and thermionic emission. Detailed information is required on the electrical conductivity, the thermal conductivity and the distribution of energy as among electrons, ions and atoms in differing forms of high-temperature plasma. A preliminary study has been made of discharge 'temperature' and of departures from the thermal equilibrium in arc discharges under a variety of conditions. Currents up to 200 amp. d.c. and 1,000 amp. peak pulse have been used in various gases at pressures from atmospheric down to 10^{-7} atmosphere and subjected to magnetic fields up to 1,000 gauss. It has been found that spectroscopic measurements of temperature may be misleading if the precise behaviour of the discharge is not taken into account.

Division 3 deals with switchgear, transformers and power system behaviour. An interesting study of the so-called anomalous loss in iron undergoing alternating magnetization has been made at the laboratories of the British Iron and Steel Research Association on behalf of the Electrical Research Association. The problem has been examined theoretically on the basis of domain concepts. and it has been shown that for strip thicknesses down to 0·01 in. calculation predicts satisfactorily the total eddy current loss. Calculation on a classical basis may give results differing from the measured eddy loss by as much as 30 per cent of the total loss. With thinner sheets there is still an anomaly, and the hypothesis that this may be due to the locking of domain boundaries by imperfections is being examined.

It has been found in practice in the impulse testing of transformers that an impulse applied to one winding could induce in other windings voltages much higher than would be expected. This phenomenon has been demonstrated on a model and has been examined on a large production transformer by exploration with a capacitance probe.

Lines and cables for power supply comprise the field of Division 4. The rating of cables and allied problems have again attracted a good deal of attention. Methods of calculation are being reviewed as a contribution towards a programme for the international standardization of the calculation of cable ratings. Experimental work has continued on the short-circuit ratings of a range of paper-insulated, mineral-insulated and polyvinyl chloride-insulated cables.

A good deal of the effort of Division 5, "Non-industrial Applications," has been devoted to off-peak floor heating. Direct observations have been made on the relations between the constructional features of buildings and the temperature distribution with time throughout heated floors, and these have been accompanied by studies made on the Electrical Research Association's network analyser involving a wider range of parameters. These laboratory experiments are being supplemented by records obtained from occupied flats. Several floors in two new blocks of flats in the London area have been modified in accordance with the Association's recommendations and have been fully instrumented for the measurement of heat-flow and temperature distribution.

A related problem, that of the prevention of ice formation on limited areas of road surface, is being studied on the installation at the Mound, Edinburgh. Recordings are being made of the temperature distribution and heat transfer produced under a wide range of weather conditions by the heating mat.

Reductions have been made fairly recently in the bulb sizes of certain electric lamps. As a result, for a given wattage, higher temperatures are encountered, and a preliminary investigation has shown the need for modifications in lampholders and fittings. It has been represented to the British Standards Institution by the Electrical Research Association that there is an urgent need for the production of a standard lampholder of insulating material capable of withstanding the temperatures which are now attained.

In the same section are recorded the Association's activities concerned with rural electrification, farming and horticulture. In collaboration with the National Institute for Research in Dairying laboratory tests have been carried out on a dairy heat-pump, and the plant has now been installed on a farm for trial under practical conditions. A preliminary study has also been made of the application of the heat-pump principle to bulk milk-tanks on farms.

Division 6 of the report deals with industrial applications. Work on flameproof enclosures has continued and it is noted that, for the Ministry of Aviation, a determination of safe gaps for ¼-in. and ⅛-in. flanges has been made for propane as representative of petroleum spirit. Research in the related subject of the intrinsic safety of electric circuits in explosive atmospheres has comprised, along with the extension of the range of gases studied, an investigation of the incendivity of propane–air mixtures for break sparks produced in circuits of low voltage, 0·5–2 V. It is found in such circuits that the ignition energy comes almost wholly from the stored inductive energy, that contributed directly from the supply being negligible.

Work on material transfer in welding arcs has concerned both the stable small droplet, the large globule and the transition region. The possibilities of enforced transfer by electrical means are being investigated for aluminium and for some related materials. The investigation of the long-term stability of fixed resistors under various conditions of operation or of storage continues. The present work is concentrated on standard size metal oxide film and evaporated nichrome film resistors together with miniature oxide film resistors. The behaviour of fuses is being re-examined both experimentally and theoretically in respect of the effect of the pre-heating of the fuse.

An investigation started during the year aims at the collection of data on the occurrence of short-duration transients in low-voltage distribution systems. Such transients are known to cause damage to electronic apparatus and the immediate purpose of the investigation is to collect information as to the frequency of occurrence and the amplitude-level of these disturbances. Preliminary results indicate that pulses of the order of 50 V amplitude happen frequently, but those of 400 V or more only occasionally.

The text of the Director's report concludes with paragraphs on member relations and on the information bureau and library. Then follows a complete list of the research reports issued during the year and of published technical contributions. The structure and composition of the Divisional and Research Advisory Committees are set out in full and—a particularly valuable feature—the scope of each is briefly stated.

J. Greig

SOLID-STATE PHYSICS

A PLEASANTLY informal meeting on several aspects of solid-state physics took place in the pure physics division of the Canadian National Research Council at Ottawa. The meeting occurred during the week of June 18–22. The main purpose was to bring experimentalists and theorists together in an informal atmosphere so that an uninhibited exchange of views and ideas could ensue. Three main areas were explored; electron transport in metals, anharmonic effects in crystals, and basic problems in metallurgy.

The discussions on electron transport theory were opened by Dr. M. Bailyn (Northwestern University, Evanston, Illinois), who outlined a new variational method that could be useful in magneto-resistance problems. This was followed by a discussion between Dr. J. Ziman (University of Cambridge) and himself on the difficulties of obtaining reliable numerical values for low-temperature transport coefficients. From this exchange of views it was evident that both the shape of the Fermi surface and of the phonon spectrum will have to be taken into account before any 'reliable numbers' can be produced from the theory. Dr. Ziman also gave an account of some of the recent developments in the theory of liquid metals. He pointed out that there is a striking correlation between the values of the electron-'phonon' coupling constant obtained from the resistance of liquid metals, and the transition temperatures of superconductors. Dr. G. Chester (University of Birmingham) opened a discussion on the physical interpretation of the present-day theory of superconductivity. Dr. D. K. C. MacDonald (National Research Council of Canada) raised the question as to whether there is any theoretical upper limit to superconducting transition temperatures T_c. The only theoretical answer that was forthcoming was that if the transition was mediated by electron–phonon interactions then T_c will always be very much less than the Debye temperature. Otherwise, no sound theoretical limit could be given.

Dr. Barron introduced the topic of anharmonic effects in crystals. He pointed out that from the point of view of statistical mechanics it is possible to include some part of the anharmonic effects by redefining the phonon frequencies. This idea raises the interesting question as to how far it is possible to carry through this idea of introducing 'effective phonons' to account for anharmonic effects. In other words, to what extent can we talk in terms of effective (or re-normalized) phonons in crystals in the same way as we talk of effective (or quasi) particles in a fermion system? This question has not yet been fully explored theoretically.

Prof. F. R. N. Nabarro (University of the Witwatersrand) reviewed the properties of dislocations and discussed the present state of theories of deformation and strain hardening of crystals. It was concluded that further experimental work is required to determine the relative importance of the various possible obstacles to dislocation motion, namely: (1) the long-range stresses due to groups of dislocations piled-up on the primary slip plane; (2) the stresses due to forest dislocations on intersecting slip planes; (3) the resistance to motion of the jogs on dislocations. The danger of relying too much on observations of surface effects was emphasized. Stereo-pictures shown by Dr. Z. S. Basinski (University of Ottawa) illustrated convincingly the three-dimensional complexity of the dislocation arrangements observed by electron microscopy. Results showing the variation of stacking fault energy with composition in a number of alloy systems were presented by Dr. A. Howie (University of Cambridge) and the relation of this quantity to the mechanical properties and electronic structure of crystals was discussed.

One of the major problems in present-day physics is that of communicating effectively between different groups of physicists. A meeting such as this can provide exactly the right atmosphere to break down the 'language barrier' between experimentalists and theorists. The efforts of Dr. D. K. C. MacDonald and Dr. J. S. Dugdale (University of Ottawa) in organizing the meeting were greatly appreciated by the visitors, all of whom appeared to enjoy both the meeting and their visit to Ottawa.

G. V. Chester
A. Howie

A PHILOSOPHY OF LIBRARIANSHIP

THE Library Association has issued as *Occasional Papers* No. 3 the address "The Creed of a Librarian—No Politics, No Religion, No Morals"—given by D. J. Foskett at a meeting of the North Western Group, Reference, Special and Information Section in Manchester last March*. Mr. Foskett directed attention to the fact that the attitude of the professional man to the body of knowledge and technique that constitutes professional equipment is coloured by a sense of purpose, and the ordering of that knowledge in the professional mind is inspired and directed by the end for which it is acquired. The formulation of a professional creed is bound up with professional education, and it is in the formation of an attitude of mind that we can distinguish between education and mere training. For the basis of a librarian's philosophy, he believed, one must look to the ideas of Mr. Raymond Smith that a library is part of a social organization and that librarianship is a social process inextricably bound up with the life of a community. It was in special libraries that the place of the active information service in the progress of knowledge could be most clearly seen—the library playing its part alongside the other members of the organization, to promote the welfare of the organization by implementing its policy through books.

Librarianship, he pointed out, like all processes, was a dynamic continuum, and the refinement of techniques, such as classification and indexing to provide a better service, was being done mainly by special librarians. The most sustained attempt to work out a philosophy of librarianship was that of Dr. Ranganathan, and his few basic laws expressed in a few short phrases the philosophy of Raymond Smith, that knowledge increases, the people need knowledge, and that the function of the library is to see that they get it. Librarians, Mr. Foskett argues, are the key figures in the process of organizing the flow of information from producer to user, because they deal directly with the reader. However, if they were to provide readers with the sort of reading that they wanted, some close knowledge of readers was necessary, although bringing readers and their material together remained basically a matter of organization. In reference service the librarian should be the reader's *alter ego*, immersed in his politics, his religion, his morals. He must have the ability to participate in the reader's enthusiasms and to devote himself wholly and whole-heartedly to whatever cause the reader has at the time of his inquiry. This involves also looking ahead and trying to correlate the new information pouring daily into the library with the known requirements of its users. Furthermore, one of the most useful functions the librarian could perform to-day is that of taking a broad view, of seeing those factors that are common to many fields, of widening the horizon of the reader, and assisting the cross-fertilization of ideas. A librarian, too, should have strong personal convictions and to be efficient must be dedicated.

---

DIET OF THE NEW-BORN HUMAN BEING

BABIES at birth have almost no powers of discrimination in choosing their food. This is perhaps scarcely surprising from the evolutionary point of view; until asepsis was invented, there was only one kind of food that enabled a baby to grow. Now, with many forms of relatively safe infant foods easily available, someone, usually the mother, makes a deliberate choice on behalf of the baby.

This choice is subject to custom, even to fashion, and is often determined by trivial circumstances rather than based on any comprehensive view. This is also not surprising; the comparative merits of human and other kinds of milk are often important for domestic or commercial reasons, but there have been few sound surveys from which to form an opinion on their relative values for the new-born human infant.

Among the notable surveys is one that was carried out in the mid-1950's in two areas of Norrbotten, the northernmost county of Sweden, lying partly within the Arctic Circle and which is described in a recent issue of *The Glaxo Volume* (No. 24). The population is predominantly Swedish with some Finnish and Lapp minorities, and is concentrated in the valleys and coastal areas. The climate is hard, and temperatures of –30° to –40° C are not uncommon in winter. Most of the inhabitants of one area investigated, Kiruna, were workers in a large iron mine. In the other area, Tore-Ranea, most were smallholders. In this county large families are still common, and nearly one-quarter of the babies were fed from the breast for more than six months. The survey has given much careful clinical observation, along with biochemical findings, for comparing the growth and health of infants whose different methods of feeding were recorded.

Frequent examinations by doctors and nurses were made throughout the first year of the babies' lives and continued less frequently up to two and a half years; they were interrupted only by the coldest weather or by the impassability of the roads. The children studied were 402 of the 660 born alive in the area during a period of eighteen months. In the two and a half years of the follow-up, only two died after the neonatal period.

The investigators classified the babies into four groups, according to how long they were fed only from the breast (0–2 weeks; 1–2½ months; 3–6 months; over 6 months). To simplify comparisons, all artificially fed babies received the same milk mixture, consisting of equal volumes of cows' milk and water, with added sugar and a little flour. This provided less protein than is normally received by bottle-fed infants in many parts of the world.

There was no great difference in weight-gain attributable to the type of feeding until about the fifth month, when the babies weaned early from the breast gained faster than the others. Here an old difficulty was encountered in comparing infant foods. The secretion of milk by a mother can be too small for her baby. When a comparison is made between a group of babies continuing to receive human milk and one fed by another regimen, it is inevitably affected by the prevailing view about when a baby should be given supplementary food. Thus it may not measure the simple effect of an unlimited diet of human milk.

Another difficulty is the uncertainty of how quickly a baby ought to grow. To some extent the individual baby, by his demands and by his end-point of satiety, settles how much he will take. This is clear enough when weight curves are drawn for the two sexes. Baby boys gain on average faster than girls and take more milk, even in the first six days of life. Presumably their appetites differ. But within the pattern of individual and sex differences, it is possible to cause some departure from an average gain in weight by altering the food. There appears to come a time when the underfed baby, who after a briefer period on a smaller diet would have voluntarily made up the deficiency, comes to accept small feeds and to grow slowly. There is also the reverse of this, the baby who has always been pressed to take more. It appears that some babies become habituated to extra food and to maintaining a high rate of growth.

In the Norbotten survey the half-strength cow's milk gave an average gain in weight in the first months slightly less than that of the breast-fed babies. In other surveys the bottle-fed have gained weight considerably faster, and this greater gain in weight has been accepted by mothers and pædiatricians alike as an argument in favour of cows' milk. An undercurrent of doubt has now to be taken into account, for it may be that early fast growth brings early maturation, possibly with extra problems and perhaps also early decline, though perhaps also with greater early achievement. These surmises are partly justified by McCance and Widdowson's findings in rats. How far they apply to human development is not known.

Although gain in weight in the first months among the Norrbotten babies differed little, despite the different diets, the babies fed early from the bottle were longer at seven and a half months than those breast-fed; any difference had disappeared by thirty months. Ossification centres in boys did not differ between groups, but in girls significantly more ossification centres had appeared at seven and a half months in those fed early on cows' milk. Girls were known to have more ossification centres than boys at that age, but the relation of this to diet had not been observed before. By thirty months the groups showed no marked differences related to diet or sex.

In Norrbotten, the times at which the deciduous teeth erupted were found to be unaffected by diet. The incidences of caries in breast-fed and bottle-fed infants were ingeniously compared. Its occurrence on the surface of teeth largely mineralized before two months was compared with that of teeth mineralized later in the same child. In this way, although the individual range of caries was wide, it was found that teeth mineralized late were slightly but significantly more susceptible to caries if the baby had been entirely breast-fed up to the time of mineralization. The fluorine content of the water was about 0·1 mg per litre; all children received vitamin D and no radiological evidence of rickets was found.

Although the clinical measurements of calcification varied so little with the kind of milk given, the total intake of calcium and phosphorus was estimated by the Norrbotten workers to be much greater from the diluted cows' milk than from the human milk. The serum calcium was, however, higher among the breast-fed. This reflects, as McCance has pointed out, lower intake of phosphate from human milk limiting the deposition of calcium, rather than differences in the content of calcium itself.

As in other surveys, the incidence of most infections was greater among the babies weaned early. Most of the babies fed from the breast for more than six and a half months came from large families, and the consequent likelihood of greater exposure to infection may have masked other differences. The sedimentation-rate was significantly lower among the babies fed from the breast than among the bottle-fed. The bottle-fed had more pyrexial attacks, but this was due to some babies having several attacks.

Although the amount of upper respiratory infection was not significantly different between the groups, there was more bronchitis and more otitis media among the early weaned, and in one area, more diarrhœa. The number of babies suffering from acute exanthemata was too small, as would be expected, to provide useful statistics. Nevertheless, the trend in the figures conforms with the clear evidence in Douglas's survey that there was less measles among the babies fed longest from the breast.

The antibodies of human colostrum and milk, imprinted as they are with the mother's immunity, may give some protection to the baby, not so much by being absorbed as by coating, and later causing the lysis of ingested organisms. There are some possible mechanisms involved in defence that depend on the diet.

The relative protection against measles conferred by breast feeding would have been expected to be associated with a higher serum γ-globulin, but the Norrbotten survey shows clearly that babies fed for the longer time from the breast had in fact a significantly lower γ-globulin level. Although γ-globulin given by injection can confer immunity to measles, the relatively high γ-globulin induced by feeding with cows' milk does not apparently give this protection. The high γ-globulin content of serum in the group of babies weaned early might be the result of an immune response by the baby to some substances in cows' milk.

This classical Norrbotten survey was undertaken by Prof. Olof Mellander, Prof. Bo Vahlquist and Dr. Tore Melbin, with twenty-three named assistants and many others taking part besides. Between them they made hundreds of thousands of observations. Those who live in other climates must admire their achievement in a region where for a large part of the year darkness heavily predominates.

GUTENBERG'S EARLY *PKP* OBSERVATIONS

By Dr. BRUCE A. BOLT
Department of Applied Mathematics, University of Sydney

IN several important papers, Gutenberg[1-3] has directed attention to seismic waves recorded as first arrivals at epicentral distances, Δ, between about 125° and 140°. At the shorter distances in this range the waves arrive between 15 and 20 sec earlier than the normal *PKIKP* waves. The early onsets are generally of such relatively small amplitude and short period that they "may be missed sometimes in reading the records[4]". Seismograms showing the small onsets and the larger *PKIKP* onsets which follow them are reproduced in Gutenberg's papers[1,3]. In a special study of seismograms from the deep-focus New Zealand shock of December 10, 1958, I have found a number of other clear examples.

These early waves cannot be interpreted solely in terms of reflexion, refraction, diffraction and the present theories of the structure of the Earth's core. Gutenberg's tentative explanation[4] was in terms of wave dispersion in a transition region between a liquid outer core and a solid inner core.

In this communication I present a new explanation of the early waves, which is based on ray theory. By successive approximations, a velocity distribution for the core has been derived which is reasonably consistent, within the limits of the empirical data used, with:

(*a*) a set of travel-times of the early waves measured by Gutenberg ;

(*b*) the Jeffreys–Bullen travel-times for the main *PKP* branches ;

(*c*) seismic ray theory for a spherically symmetrical Earth.

It follows that the relation between the derived velocity distribution and the actual structure of the Earth's core depends on the physical correctness of (*a*), (*b*) and (*c*). The Jeffreys–Bullen tables were taken as a basis for the work since these times are widely adopted as standard for an 'average' Earth.

The Jeffreys–Bullen travel-times for *PKP* are based on the hypothesis[5-7] that an inner core exists having a discontinuous change of velocity at its boundary. The velocity solution[8] which corresponds to the Jeffreys–Bullen times is drawn in Fig. 1. (Hereafter it is called the *J* velocity solution.)

The assumption of a single velocity jump yields a travel-time curve similar to the diagram in the left corner of Fig. 2. The grazing ray at the mantle-core boundary (radius R_c = 3,473 km) is refracted to *A* near 180°. Rays more steeply incident on this boundary give in turn the branches *AB* and *BC* until the ray at *C* grazes the inner core. The branch *BC* is generated by rays reflected from the inner core, and *DEF* by the *PKIKP* rays refracted through the inner core.

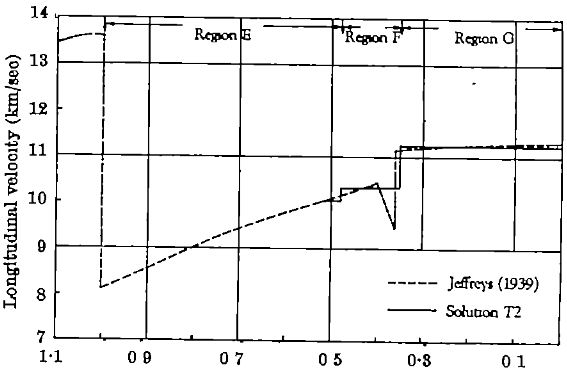

Fig. 1

A caustic curve is located near *B*: for distances slightly beyond *B*, points on the Earth's surface can be reached by two refracted rays with consequent reinforcement of energy. Large *PKP* amplitudes are commonly observed[3] at epicentral distances between 143° and 147°.

Numerous observational studies of the *PKP* phase have been made[6,7,9]. (Some evidence[10,11] indicates that the Jeffreys–Bullen times for *PKIKP* need an increase of about 1·5 sec relative to the *P* times for Δ > 80°). Additional recent data on *PKP* from an East Indies shock of April 16, 1957, have been published by Gutenberg[3]. Stations with 118° < Δ < 140° at which Gutenberg made confident interpretations are listed in Table 1.

The residuals in columns I and IV are the differences (*O–C*) between the observed travel-times of the first and second onsets and the corresponding Jeffreys–Bullen times for the *DE* branch of *PKP*. A focal-depth of 600 km, used by Gutenberg, has been adopted, while Gutenberg's origin-time has been increased by 7 sec to 4 h 04 m 11 s to shift the mean *PKIKP* residual to zero. The early onsets at the 22 stations with

J–B, Jeffreys–Bullen

124° < Δ < 140° constitute the set of empirical times mentioned in (*a*). The corresponding residuals range from −21 to −10 sec.

We now consider the hypothesis that there is a double positive jump in longitudinal velocity within the core. In the usual notation, let the two discontinuities at radii R_F, R_G ($< R_F$) divide the core into Region *E*, Region *F* and Region *G* (the inner core).

An initial restriction in accord with (*b*) is that the velocity jumps must not affect the position of the well-observed caustic at *B*. This requires that $0 \cdot 54\, R_c > R_F$, approximately. A possible form of the new *PKP* travel-time curve is sketched in Fig. 2. There are now six branches and five cusps *B*, *C*, *G*, *H* and *D*. The *CG* branch arises from reflexions from the outer boundary of Region *F*; *HD* from reflexions from Region *G*. The effect of the new hypothesis is to introduce a branch *GH* which is earlier than the *DEF* branch and which may be associated with early *PKP* observations with Δ > 120°, approximately.

A considerable amount of numerical analysis was undertaken to obtain a model consistent with (*a*) and (*b*). Two main problems are to reproduce the positions of the cusps *D* and *G*, and also the gradients $dt/d\Delta$ of the observed branches *AB*, *GH*, *DEF*. As a sufficient approximation for the present purposes, the velocities v_F, v_G were taken constant in all trial models.

The *J* velocity distribution (cf. Fig. 1) has a velocity decrease outside the inner core. In order not to exceed the measured travel-time of a diametrical *P* wave when the second velocity jump at R_F is introduced, and at the same time to obtain the required gradients of the branches, the *J* velocity gradient was reduced to zero just above Region *F*. Let the upper boundary of this region be R^*. For $r > R^*$, the *J* velocities were adopted unchanged. As a consequence, in all the trial solutions the times of the branch *AB* and part of *BC* are identical with the corresponding Jeffreys–Bullen times.

The requirements (*a*), (*b*) and (*c*) were found to place strong constraints on the possible ranges of the free variables R^*, R_F, R_G, v_F, v_G. Two solutions, called *T*1 and *T*2, for the models defined in Table 2 are presented here; the differences between them indicate the effect of a change in the variable R_F. Table 2 gives also the times, distances and gradients at the cusps. Times for reflexion at R_F were calculated using:

$$t = 2\int_{R^*}^{R_C} r^{-1}\,\eta^2\,(\eta^2 - p^2)^{-1/2}\,dr$$

where $\eta = r/v$, and $p = dt/d\Delta$. The usual associated integral[13] gave the corresponding distances. Since the integrands become large as $r \to R^*$, Weddle's rule, which requires constant fifth differences only, was used towards R^*. After building up the core times for *K*, these were combined with the Jeffreys–Bullen *PcP* times by selecting points with equal gradient *p*. Various checks suggest that the times and distances in Table 2 are probably accurate to about half a unit.

Table 2

	Solution *T*1				Solution *T*2			
	km			km/sec	km			km/sec
R^*, v^*	1,806	($0 \cdot 52 R_c$),		10·08	1,806	($0 \cdot 52 R_c$),		10·08
R_F, v_F	1,598	($0 \cdot 46 R_c$),		10·32	1,667	($0 \cdot 48 R_c$),		10·31
R_G, v_G	1,216	($0 \cdot 35 R_c$),		11·25	1,216	($0 \cdot 35 R_c$),		11·23
	Time		Δ°	*p*(sec/1°)	Time		Δ°	*p*(sec/1°)
	m	s			m	s		
Cusp *C*	20	00·7	152·1	2·78	19	56·2	151·2	2·90
G	18	47·0	125·6	2·70	18	41·9	124·7	2·82
H	20	6·2	156·2	2·05	20	6·3	156·5	2·05
D	18	36·2	111·3	1·89	18	37·5	111·0	1·89

The branch *DEF* for both *T*1 and *T*2 agrees within a second or two with the Jeffreys–Bullen times for *PKIKP*. The residuals of the first onsets from the East Indies shock against the *GH* branches of *T*1 and *T*2 are listed in columns II and III of Table 1. The 19 observations at the more distant stations give mean residuals of − 3·2 ± 0·4 sec and − 0·2 ± 0·4 sec against *T*1 and *T*2 respectively. A comparison with the remaining observations suggests that the measured onsets at Lick, Tinemaha and Isabella may be late through weakness. Agreement between the predicted and the empirical times appears close enough to warrant further consideration of the new hypothesis. On the data of Table 1, solution *T*2 is to be preferred; its velocity distribution is plotted in Fig. 1.

The values of *p* in Table 2 show that an increase of only 0·7 sec/1° in the ray parameter *p* yields a length of about 30° for the *GH* branch. The corresponding rays therefore leave the focus at nearly the same angle of incidence and relatively little energy is available for the early waves.

It is of interest also to compare the two theoretical solutions with the mean travel-times of first-arrival *PKP* waves from four hydrogen bombs exploded at Bikini[13]. To permit a comparison with the Jeffreys–Bullen tables, the mean residual δ of *P* observations from these explosions was first applied as a correction. From 232 *P* readings, with 34° < Δ < 104°, δ = 1·8 ± 0·6 sec[14]. The five adjusted mean travel-times and the residuals against *T*1 and *T*2 are listed in Table 3 (*n* is the number of observations).

The adjusted times have also been marked in Fig. 1, which shows the complete travel-time curve for *T*1. Comparison indicates that the small onsets at the five stations are in reasonable accord with the predicted travel-times based on the new hypothesis and on (*a*), (*b*) and (*c*).

Bullen and Burke-Gaffney explained the onsets at Pretoria and Kimberley in terms of diffraction near

Table 8

Station	Δ°	n	Adjusted mean travel-times	Residuals (O–C) (sec)	
				$T1$	$T2$
			m s		
Stuttgart	116·2	4	18 46 1 ± 0·6	+1	−1
Tananarive	119·8	2	18 54·5 ± 0·6	+2	0
Pretoria	137·3	3	19 16·4 ± 0·6	−1	+1
Kimberley	139·5	4	19 23·1 ± 1·0	0	+2
Tamanrasset	140·4	4	19 26·9 ± 1·1	+2	+4

the caustic at B. They remark, however, that since the early waves are about 1 sec period, Pretoria lies about 1·6° outside the range where observable diffracted waves might be expected theoretically.

The hypothesis advanced here has consequences which may provide tests crucial to it. The alteration of the J velocities for $r < R^*$ affects the times of all core phases for certain epicentral distances. In particular, for solution $T2$, SKS proper ends at $\Delta \approx 133·5°$ with a travel-time near 26 m 30 s. The corresponding time from the Jeffreys–Bullen tables is 26 m 28 s with a standard error[7] near 2 sec. In another study of recorded SKS, Nelson[15] gives 26 m 32 s at the same distance.

The observational evidence is that no large amplitudes occur near the cusps D and G. Recent theoretical work of Bullen[13] shows that under conditio which resemble those for $T1$ and $T2$, neither D nor are caustics. On the other hand, if the velocit *remained continuous* but the gradient suddenl changed at R_F and R_G these cusps might be associat with large amplitudes.

I propose to publish later a detailed quantitativ discussion of velocity solutions for the core based o the new hypothesis.

GEOCHEMICAL AND GEOLOGICAL EVIDENCE FOR THE ORIGIN OF DARWIN GLASS

By Dr. S. R. TAYLOR
Department of Geophysics, Institute of Advanced Studies,
Australian National University, Canberra
AND
M. SOLOMON
Department of Geology, University of Tasmania

THE occurrence of a frothy siliceous glass, from the eastern slopes of Mt. Darwin, Western Tasmania, was brought to scientific attention in 1910 by M. Donoghue. It was first mistaken for slag from an abandoned copper smelter. In 1913, H. Conder, State mining engineer, informed the Geological Survey of Tasmania of the occurrence, and a survey was undertaken by Loftus Hills. Samples were sent to Prof. F. E. Suess in Vienna, who named it 'Queenstownite' after the nearby town, and compared it with the moldavites[1]. Later workers have preferred the name 'Darwin glass'. Hills[2] fully described the details of the discovery and location, gave a description of the glass by Suess, and two chemical analyses by Ludwig.

A further description of the occurrence, with two new analyses by Ampt, is given by David *et al.*[3]. All these workers have agreed on the natural origin of the glass, and placed it with the tektites, although recognizing that it was an aberrant type.

Later workers, notably Conder[4], Suess[5] and Spencer[6,7], classified Darwin glass as an impactite, formed by fusion of siliceous sediments by meteorite impact. Preuss[8] reported a single determination of 240 p.p.m. chromium, 314 p.p.m nickel, 1·80 per cent iron, with a nickel–iron ratio of 170 × 10^{-4}. Ehmann[9] found 162 p.p.m. nickel and 1·60 per cent iron, giving a nickel–iron ratio of 100 × 10^{-4}, and he placed Darwin glass among the impact glasses without comment. Baker and Gaskin[10] and Baker[11] considere the glass to be of uncertain origin (no meteorite crate has yet been discovered in the vicinity) and Baker has suggested an origin by fusion of silica in burnin peat horizons. Doubt has also been cast on th authenticity of some specimens, and it seems possibl that some of the smelter slag and also some Tertiar tachylyte have been accidentally distributed a Darwin glass. We therefore decided to undertake geological and chemical examination of the occurrence, and report here the preliminary finding One of us (M. S.) is responsible for the collectio and geological description, and the other (S. R. T for the chemical data and their interpretation.

The glass is very irregular, slaggy, with twiste stalactitic forms, and with rare teardrop and dis like shapes[3]. Numerous bubble pits are present, an the pieces are consequently of very low densit (sp. gr., 1·7–2·2) and have a frothy appearanc well described by the prospectors' term, 'petrifie kelp'. The largest specimen weighed 21 g an measured 6 cm by 2·3 cm. The average weight 330 specimens described by Fenner[12] was 0·57 g; th average of 41 pieces in the University of Queenslan collection was 1·61 g[13]. The density of the powdere glass varies from 2·275 to 2·296 g cm^{-3} and th refractive index from 1·474 to 1·479[3]. Twisted an bent particles of fused silica (lechatelierite) ar present, but later investigators[11,13] have failed to confirm the presence of metallic spherules reported by Conder[4].

The glass is abundant on the east slopes of Ten Mile Hill, which lies 12 miles south-south-east of Queenstown, and occurs sparsely in scattered areas within a zone ½–1 mile wide that extends north from Ten Mile Hill for about 6 miles. Glass probably occurs to the south also but dense vegetation prohibits further observations. The largest (up to 6 cm long) pieces are found at Ten Mile Hill; the average size decreases northwards and eastwards and at the northern limit of the zone of occurrence all the pieces are less than 1 cm long. The glass fragments are scattered in the peaty soil cover, which varies from a few inches to 18 in. in thickness. Many pieces appear broken but there is little evidence of stream-rounding. The shallow depth of occurrence and the lack of abrasion indicate that the glass is no more than a few thousand years old and formed or fell on a surface that has since been only slightly modified.

Within the zone of occurrence there are four rock types, steeply dipping and outcropping in north–south strips (parallel to the zone of distribution). From west to east across the zone these are:

(1) Sheared volcanics, mainly intermediate in composition. Mt. Reade Volcanics (Cambrian).

(2) Well-sorted, coarse-grained quartz sandstone, and conglomerate. Owen Conglomerate (Ordovician).

(3) Dark grey fossiliferous limestone and dark grey shale. Gordon Limestone (Ordovician).

(4) Coarse-grained quartz sandstone. Crotty Quartzite (Silurian).

Darwin glass is found on each of these beds but mainly on the Owen Conglomerate and the Crotty Quartzite. These two formations, together with quartzose rocks from the Silurian and Precambrian, underly more than 50 per cent of this part of the west coast of Tasmania. Glass has been found on the volcanics in only one place (south-west of Darwin) but because it is highly improbable that it has been transported there, this occurrence precludes the hypotheses involving *in situ* origins (for example, fulgurites).

Hills[3] is correct in saying that the glass cannot be slag, because it is within soil that was formed prior to modern occupation and the glass is not at all like the slag from the Crotty smelters (from physical appearance, thin sections and composition). The Mt. Read volcanics do not contain glass.

Table 1. AVERAGE COMPOSITION OF MAJOR CONSTITUENTS IN DARWIN GLASS[2,3] (COL. 1), AOUELLOUL GLASS[13] (COL. 2) AND AUSTRALITES[15] (COL. 3)

	1	2	3
SiO_2	87·98	86·51	73·45
Al_2O_3	7·04	5·76	11·53
Fe_2O_3	0·36	1·30	0·58
FeO	1·54	1·59	4·05
MgO	0·76	0·91	2·05
CaO	0·11	0·73	3·50
Na_2O	0·11	0·14	1·28
K_2O	1·07	2·05	2·28
TiO_2	0·78	0·55	0·70
Σ	99·75	99·54	99·42

A preliminary age determination has been made on a typical sample through the courtesy of Dr. W. Compston. The total rubidium content was 75 p.p.m., total strontium was 15 p.p.m., and the strontium-87/strontium-86 ratio was 0·810. Assuming an initial ratio of 0·710, an age of 450 × 10^6 years is obtained. Until similar work is carried out on possible parent materials the significance of this age is obscure.

Four chemical analyses have been published[2,3] and the average of these is given in Table 1. The average of two analyses[13] of the glass from Aouelloul Crater in the Western Sahara is included in Table 1. Campbell Smith and Hey[13] have directed attention to the remarkable similarity of these two glasses, both in form and composition. The black and white glasses from Wabar[16] are also analogous in composition and the black glass is very similar in appearance to Darwin glass. Further analyses of the major constituents are being carried out by Dr. H. B. Wiik, and a full discussion will be given elsewhere.

Determinations of trace elements, and some major constituents on eight samples have been carried out, and averages of these data are presented here. Full details of the sample preparation and analytical methods will be given elsewhere. Care was taken to ensure that the samples were clean, and to avoid contamination during crushing. The glass was quite friable, and was disintegrated readily in an iron–manganese steel mortar, followed by grinding, to pass 120-mesh bolting cloth, in an agate mortar.

The elements were determined by emission spectrography using the general procedures described by Taylor[14,15]. Analyses for the alkali elements were carried out with a large Hilger glass prism spectrograph, using Kodak *IN* plates, and sodium as a variable internal standard. Sodium and potassium were determined using a Perkin Elmer model 146 flame photometer. The remaining elements were determined using a Jarrell-Ash Ebert grating spectro-

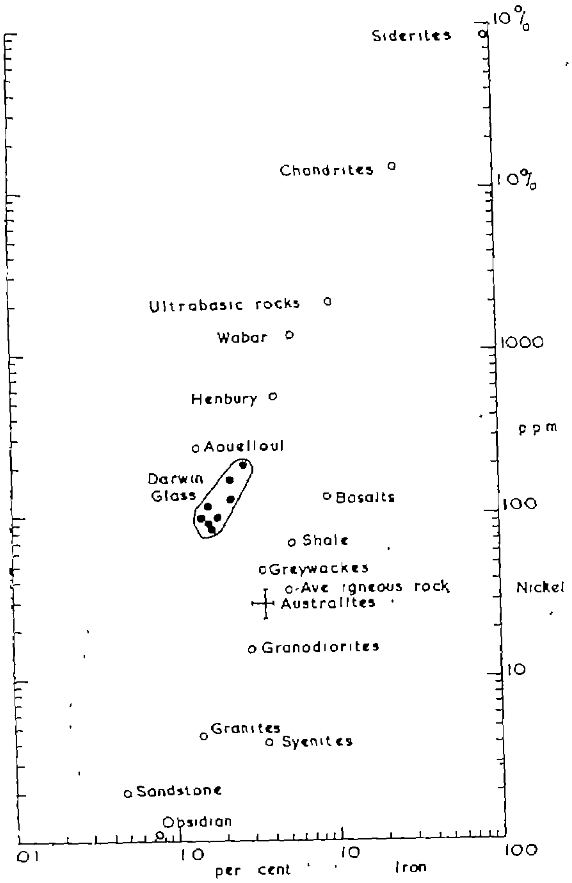

Fig. 1. The relationship between iron and nickel for Darwin glass, meteorites[18], australites[15], impact glasses[9,13 18,19] and common terrestrial rocks[16,17]

graph. The wave-length range from B 2497 to Ba 4934 was recorded on Kodak 103-0 plates, using palladium as an internal standard. The analytical precision of the methods is given in Table 2. Mixtures of the standard granite *G*-1[16], the U.S. Bureau of Standards silica brick 102 and glass sand 165 were used as reference standards.

The results are given in Table 2. The overall average of eight samples is given in the first column, followed by the averages of two distinct groups, the first with two samples and the second with six. The next column gives the analytical precision, expressed as a relative deviation. This is in general satisfactory, but precision falls at low levels, for example, strontium, lithium, scandium, or where substantial corrections for background have to be made, for example, yttrium.

Average compositions for australites[15], sandstones[16,17] and chondritic meteorites[18] are given for comparison. The trace element data show a general similarity with that for sandstones, except that sodium is lower, and iron, and, in particular, nickel and chromium (and cobalt in group I), are significantly higher in the glass. The presence of high concentrations of titanium and zirconium is to be expected in sandstones containing resistant minerals such as rutile and zircon. The high concentrations of iron and nickel are consistent with a meteoritic impact.

The comparison with australites is interesting. Potassium, rubidium, copper, titanium and zirconium have about the same concentration. Iron and barium are about half as abundant, and lithium, sodium, strontium, vanadium, manganese and scandium are depleted by larger factors in Darwin glass. These are the sort of changes to be expected with an increase in silica content of about ten per cent. Nickel, chromium, and, in group I, cobalt, are markedly more abundant in Darwin glass compared with the australites.

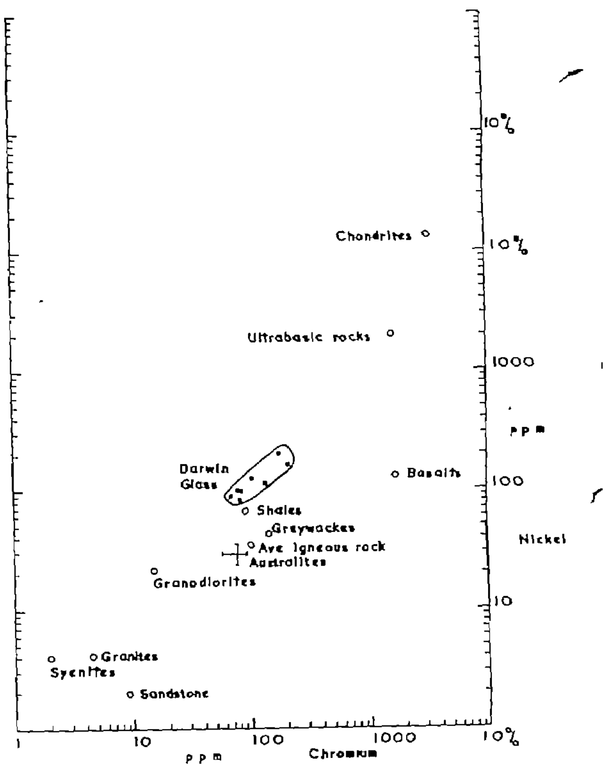

Fig. 2. The relationship between nickel and chromium for Darwin glass, meteorites[18], and common terrestrial rocks[16,17]

The relationships of iron, nickel and chromium in Darwin glass, in australites, meteorites, and a variety of terrestrial rocks are shown in Figs. 1 and 2. These diagrams clearly indicate the distinctive composition of the glass for these elements. The iron–nickel diagram (Fig. 1) illustrates the similarity with the undoubted impact glasses from Henbury and Wabar[19], and the probable impact glass from Aouelloul[9]. Data on chromium and other trace elements are not yet available for these samples.

MOISTURE EXPANSION OF A CERAMIC BODY AND ITS INTERNAL SURFACE AREA

By Dr. W. F. COLE

Division of Building Research, C.S.I.R.O., Highett, S.21,
Victoria, Australia

NORRIS *et al.*[1] have shown that for an earthenware-type body fired above the temperature of the moisture expansion peak at 1,000° C, moisture expansion and internal surface area follow parallel courses, but below 1,000° C they move in reverse directions. A similar relationship exists for the fired kaolinite-hydrous mica-quartz clay (*A* and *D*, Fig. 1) which I have recently described[2]. Norris *et al.* state that a detailed study of the cause of this relationship would throw valuable light on the mechanism of moisture expansion. It can possibly be explained as set out here, but other problems then arise.

A difficulty in comparing the moisture expansion of a ceramic body with its internal surface area is to differentiate between the internal surface area that is associated with active surfaces and that which is associated with inactive surfaces under the appropriate exposure conditions. Thus the large surface of low-burnt bodies (burnt below 900° C) is not active to water vapour in the air but is active to steam at pressure[3]. For bodies fired to high temperatures the small surface area is not active to air, or to steam initially, but in the autoclave active surfaces are generated by the leaching action of the steam on glassy materials[3]. A peak in the curve of moisture expansion against firing temperature for natural exposure and for steam exposure arises from the formation of an active phase in the bodies on firing at the temperature of the peak. From my results[2,4] this active phase is an amorphous aluminosilicate. Thus the surfaces to be sought are those developed on the formation of this material. They may be found by calculating surface areas from pore size distributions.

The pore size distribution of the kaolinite-hydrous mica-quartz clay recently described by me[2] has been given by Hill[5] (Brick Clay No. 2), and the distributions corrected for ink bottle pores by use of the retention factor as suggested by Hill[5] are plotted against firing temperature in Fig. 2. The corrected pore size distributions are used because Hill has shown that the

Table 1. SURFACE AREAS CALCULATED FROM PORE SIZE DISTRIBUTIONS AFTER CORRECTION FOR INK BOTTLE PORES, NUMBER OF POSSIBLE LAYERS OF WATER MOLECULES ON THE SURFACES, AND NATURAL MOISTURE EXPANSION AFTER 90 DAYS FOR A KAOLINITE-HYDROUS MICA-QUARTZ CLAY FIRED FROM 800°–1,100° C.

Firing temperature °C	Total surface area m^2/g	No. of layers of water molecules on total surface		Surface area from pores 0·77μ–0·2μ diameter m^2/g	No. of layers of water molecules on surface of pores 0·77μ–0·2μ diam.		Natural moisture expansion after 90 days	
		Sample undried	Sample dried at 110° C		Sample undried	Sample dried at 110° C	Sample undried per cent	Sample dried at 110° C per cent
800	9·14	5	2	0·10	436	165	0·034	0·016
900	7·50	4	1	0·14	219	79	0·093	0 072
1,000	1·92	12	8	0·24	94	25	0·190	0·136
1,100	0·48	10	4	0·10	48	21	0 062	0 053

total surface areas calculated from them are in good agreement with surface areas obtained by gas sorption methods. If natural moisture expansion is directly related to surface area over the firing temperature-range 800–1,150° C, then the pore volumes most likely involved are those with diameters between 0·77μ and 0·2μ (Fig. 2). Of the other pore volumes those with diameters between 1·66μ and 0·77μ have a complex distribution with firing temperature, but they and larger pores (not plotted) make a negligible contribution to surface area. Pores of diameters less than 0·2μ have the greatest contribution to surface area, but they tend to be a maximum at a firing temperature of about 900° C and are more likely to be associated with the development of metakaolin and mica anhydride than with the breakdown of these phases and the formation of amorphous matter at 1,000° C. However, it is possible that an unknown proportion of the pores with diameters between 0·2μ and 0·08μ, which develop in the body on firing at 1,000° C, is directly related to moisture expansion.

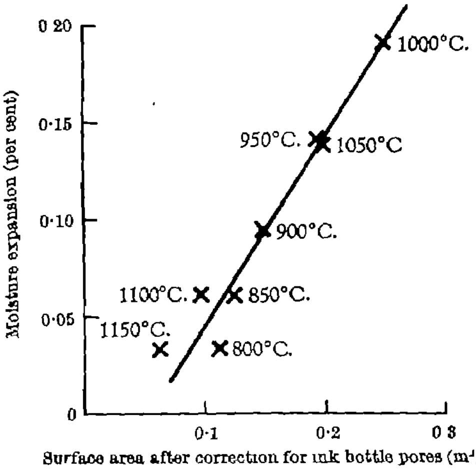

Fig. 3. Natural moisture expansion after 90 days (undried specimens) versus surface area calculated from the volume of pores with diameters between 0·77μ and 0·2μ (after correction for ink bottle pores) for a kaolinite-hydrous mica-quartz clay fired from 800–1,150° C. Firing temperatures are indicated

The results of computing the surface areas from the corrected pore size distributions of the volume of pores with diameters between 0·77μ and 0·2μ, and between 0·77μ and 0·08μ are given in Fig. 1. The surface areas are small but they rise to a peak at about the same temperature as that at which moisture expansion is a maximum, and like it fall to lower values at higher and lower firing temperatures. Best correspondence is found for pores with diameters between 0·77μ and 0·2μ (Fig. 3). In this way a possible explanation can be given to the problem posed by Norris *et al.*[1].

If surface area is related to moisture expansion it should be possible from the increase in weight that accompanies expansion to calculate the number of layers of water molecules on the surface (assuming that the weight increase is produced by water). The results of these calculations, based on one molecule of water covering a surface area of $10·8 Å^2$, are given in Table 1. If the surface area due to pores with diameters between 0·77μ and 0·2μ is related to moisture expansion, then the associated water is more likely to be combined chemically than held by any sorption process (either physical adsorption or chemisorption) on the surface, that is, it has reacted chemically with the body. On the other hand, if it is the total surface area that is related to moisture expansion there is no simple relationship between them. However, the number of layers of water molecules on the surface could arise from the water being physically adsorbed and/or chemisorbed, and is less indicative of a chemical reaction having taken place.

The interpretation given to the mechanism by which water is adsorbed during moisture expansion was suggested by R. D. Hill.

EROSION OF TIDAL FLATS NEAR GEORGETOWN, BRITISH GUIANA

By D. D. HAWKES*

Geological Survey Department, Georgetown, British Guiana

THE coastal plain of British Guiana, which is underlain by the Demerara Clay Formation, is a low swampy area at or slightly below mean sea-level. It is mainly an accretional coast which has been built up in recent and present-day times by the accumulation of mud flats. Locally, the deposition of mud by longshore currents and wave action is temporarily interrupted by erosional periods, and this note

---

* Present address: Department of Geology, University of Birmingham.

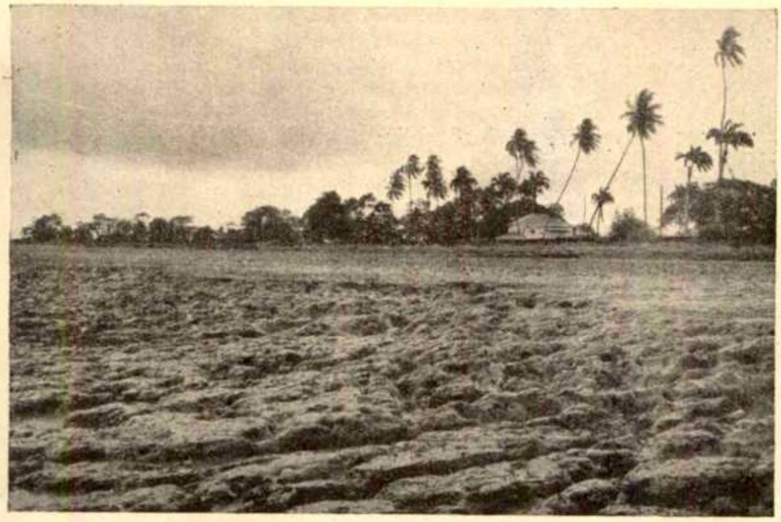

Fig. 1. The zone of intensive potholing and backwash channelling (foreground) in the tidal flat at Georgetown. In the middle distance the low cliff step and the clay platform of the upper tidal flat are seen

summarizes some of the processes of erosion of tidal flats near Georgetown. These processes contrast the commonly described methods of marine erosion in that they are most effective under conditions of calm rather than stormy weather.

A typical shore profile (Fig. 1) consists of a narrow landward zone of salt marsh vegetation, an upper tidal flat which is covered by about one foot of water at high tide, a low cliff step and then a wide mud flat extending to low-water mark. The cliff step, which marks the present limit of erosion, is formed of a stiff bluish clay and varies from one to three feet in height. Constant attack of this step takes place at high-tide by wave action facilitated by shrinkage and cracking of the clay after periods of drying during low-tide. Its retreat is most rapid in the short rainy season (December–mid-February) when the prevailing north-easterly trade winds are accompanied by heavy squalls and storms of short duration. But even in storm conditions the large expanse of mud tends to dissipate the erosive power of the waves before they reach the step. However, during the long periods of tropical calm, active erosion takes place by processes which, although less spectacular, are just as effective in the aggregate. The most potent of these is the drilling of potholes (Fig. 2) immediately beneath the cliff step.

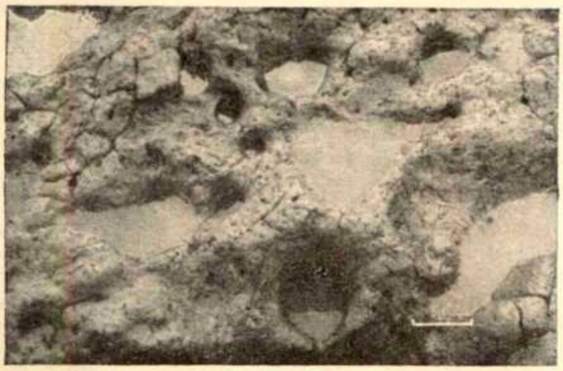

Fig. 2. Shoreline potholes formed in soft mud on the tidal flat at Georgetown. Note mud ball above the scale. Scale represents 12 in.

The formation of these shoreline potholes[1], which are essentially of the same type as river potholes, depends on the presence of a dried or partially dried clay block that is too large to be moved any distance by ordinary waves and breakers. Water swirls around this obstruction and excavates a shallow depression in the underlying soft mud into which the block sinks. It thus becomes securely fixed and can be dislodged only by exceptionally large waves or breakers. The swash and backwash of waves swirling around the obstruction impart a rotational movement to the block and the drilling of a pothole commences. In the initial stages the clay block fits tightly in the hole but later it becomes smaller and rounder (often attaining a high degree of sphericity) while at the same time the pothole becomes wider and deeper. When the pothole is well formed the included mud ball, now considerably smaller and lighter, may be lifted from the hole and thrown on to the upper tidal flat. There it may be rolled to and fro and acquire an armour, which consists mainly of hardened mud flakes. The sediment eroded from the pothole is carried away in suspension by wave-generated longshore and tidal currents, in the present case to be deposited as a mud bank some distance from the shore. Since appreciable changes in the topography of the floor may be observed even within a single 12-h intertidal period it is apparent that the drilling of potholes is a rapid and powerful method of erosion. It reaches its greatest intensity in a strip about fifty feet wide immediately beneath the cliff step. Here there is an abundant supply of fallen blocks and also the abrupt step in the tidal flat which effectively changes oscillatory waves into translation waves to create a zone of turbulence.

A large expanse of the seaward side of the clay platform (upper tidal flat) above the cliff step is strewn with armoured mud balls (Fig. 3), which vary in maximum diameter from one to ten inches. The deposit is poorly sorted and although practically all are rounded or sub-rounded only a few examples approach the perfect spherical form. The mud balls have their origin in clay blocks freshly broken from the cliff step, that are light enough to be carried over the step and transported shorewards by the swash of waves. A few highly spherical balls, as mentioned here, reach the upper tidal flat already rounded by pothole abrasion. Once on the tidal flat the blocks are rolled backwards and forwards by the swash and backwash during high tides. The balls of soft mud acquire their armour from clay flakes formed by the desiccation of the upper tidal flat at low tide.

Although they are formed in a similar manner, these mud balls differ from those described by Bell[2] in that they occur in a littoral marine environment and have an armour composed of the same material as the core. A few which are located near a shell deposit may have an outer rim partly composed of shells but the majority are perfectly homogeneous in composition and seldom contain a single foreign fragment in their armour. Further, Bell has concluded that armoured mud balls are most effective as vehicles for the transportation of bedload. In contrast to this

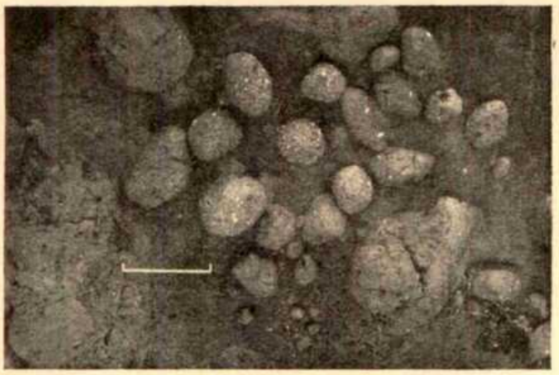

Fig. 3. Armoured mud balls. Although in the photograph shells are conspicuous these foreign fragments are subordinate to flakes of dried clay. Usually the armoured mud ball is perfectly homogeneous in composition. Scale represents 12 in.

the mud balls under discussion are powerful agents of erosion rather than transportation. Most of the armoured balls are stranded by the ebb tide and under favourable drying conditions they harden and develop an appreciable abrasive power. While in motion during high tide, especially when dragged seaward by the backwash, they tend to follow and accentuate furrows and channels in the clay platform. Some are rolled down the cliff step, where they fall into pre-existing potholes or are thrown back up again by later waves. Others, with the additional weight of their acquired armour, may attain the critical size to prevent them being carried back to the shore and will initiate new potholes.

The armoured mud balls will be preserved in the geological column only if they are completely buried by a sudden influx and deposition of sediment. This is not uncommon on tidal flats where rapid changes in the sites of erosion and deposition do occur. Th origin of the resulting deposit may not be immediatel obvious since the clay balls or nodules may b enclosed in a clay matrix of identical composition This communication is believed to be the first to sho the association of mud balls and the erosion of potholes; nevertheless mud balls from similar environments in the Mississippi Delta[3] and especially on th coast of Surinam[4] have recently been described. O the tidal flats near Georgetown clay beds which hav been deposited in historic times contain armoure mud balls. It need scarcely be added that any attemp to estimate the distance of the source materia utilizing measurements of roundness[5] or sphericity would, in the case of mud balls formed during th erosion of potholes, lead to very misleading results.

It should be stressed that the formation of shorelin potholes and mud balls is effective only in periods o calm weather since large waves and breakers ar capable of carrying the clay debris away. In tropica and sub-tropical regions where long periods of cal prevail, the spectacular methods of erosion which ar characteristic of the stormy temperate regions ma be subordinate to calm weather erosion. Certainly o the tidal flats which have been described it is apparen that the drilling of potholes is a major, if not th predominant, process of erosion. It is probable tha calm weather erosion, especially of estuarine an littoral clays, is of more importance in these region than has hitherto been realized.

This article is published with the permission of th Director of the Geological Survey Department.

CONFIGURATION OF ALGINIC ACID IN MARINE BROWN ALGAE

By DR. EVA FREI and PROF. R. D. PRESTON, F.R.S.

Astbury Department of Biophysics, University of Leeds

DURING the investigations proceeding in this laboratory into the variability of the structural polysaccharides of marine algae, we have encountered species among the Phaeophyceae containing crystalline compounds in addition to the cellulose which might be expected to form the basic skeletal polysaccharide[1]. It is well recognized that cellulose forms quantitatively only a minor component of brown algae[2]. Of the other known major constituents of these plants three can be considered in attempting to identify the additional crystalline components: (*a*) the alginates (salts of polyuronic acids); (*b*) laminarin (a β-1,3-linked glucan); (*c*) fucoidin (a polysaccharide sulphate ester) all present in variable amounts and proportions according to species, season of the year, habitat, etc.[3], but often in great excess over the cellulose. Of these, only the first two, namely, the alginates and laminarin, are known to be crystalline when precipitated from solution. They then yield X-ray diagrams containing reflexions which we also find, identical in disposition and relative intensities, in the diagrams given by t plants themselves. These plants, therefore, can co tain molecular chains of alginic acid and of laminar in orderly arrangement, and the occurrence, distrib tion and order of each of these compounds may examined by standard techniques. The wo described here is confined to the alginates, and t main technique utilized has been X-ray diffracti analysis, using copper *K*α radiation collimated to beam 0·25-mm diameter in a flat-film camera.

Alginates and alginic acid have been subjects intense investigation, largely on account of th commercial value. The chemical constitution of the polyuronides is still not completely known. In t middle 1940's, when Astbury[4] was obtaining crystallographic data, the main constituent w thought to be poly-*d*-mannuronic acid, a β-1,4-link chain polymer[5], and the X-ray diagram was attribut to this substance. In 1955 Fischer and Dörfel[6] fi proved the presence, often in large quantity, another polyuronic acid, poly-*l*-guluronic aci together with small amounts of polyglucuronic acid. They found that the two major polyuronic acids vary in proportion from 1 : 2 to 2 : 1 among the 22 species of brown algae they examined. The presence of polyguluronic acid in alginic acid has since been confirmed by other investigators[7], and the most recent work shows this acid also to be 1,4-linked[8].

Our own interest in the alginates lies chiefly in their organization within the plants and it is from this point of view that we are examining their properties. We have, however, of necessity become involved in considerations of the crystal structure of extracted alginic acid and these have yielded some unexpected results to which we shall direct attention.

Chemically untreated stipes of *Himanthalia* yield X-ray diagrams with very diffuse reflexions which are difficult to evaluate. The most intense reflexion takes the form of a broad ring or arc ranging in spacing from about 6·6 Å to about 8·3 Å (Fig. 1*a*), often with a sharper reflexion at about 8·9 Å. After washing the material in dilute hydrochloric acid a different diagram is obtained with much sharper reflexions, corresponding to markedly different spacings (Fig. 1*b*), closely similar to the diagram reported in the literature as arising from alginic acid and clearly referring to this substance. If the acid-treated material is now subjected to prolonged washing in hard tap water, or is treated with calcium hydroxide solution, the original diffuse diagram is again obtained and the material can be taken back and forth from one condition to the other by repeating these treatments in turn. On the other hand, prolonged treatment either of the original or of the acid-washed material with dilute alkali or sodium carbonate solution merely causes the corresponding diagram to disappear, leaving revealed the hitherto masked diagram of the cellulose. We conclude that the crystalline material in untreated specimens of *Himanthalia* stipes is a salt of alginic acid containing one or more divalent cations, among which Ca^{++} probably predominates. This recalls the statement made by Thiele and Andersen[9] (based on somewhat obscure arguments from the optical properties of sections) that the alginates in the Fucales and the Laminariales are ordered in the optical sense and are salts of predominately multivalent cations. Our treatment with acid and with calcium hydroxide must then convert the calcium salt to alginic acid and back again, in harmony with the change in swelling behaviour of brown algal tissues reported by Wasserman[10]. The presence of crystalline calcium alginate in these plants is further supported by comparison of the X-ray diagrams of untreated stipes of *Alaria* (Fig. 2*a*) with that of commercial calcium alginate fibres (Fig. 2*b*). Fig. 2*a* illustrates the common condition in brown algae that arcs attributable both to the alginate and cellulose (particularly the meridional arc at 5·25 Å $(10\bar{1})$) are present in the diagram. Calcium alginate is reputedly badly crystalline, as exemplified in Fig. 2, and it is not therefore surprising that our untreated material gives such diffuse diagrams. The faint possibility that the alginate may have become crystalline on drying need not be considered since the diagram of Fig. 2*a* was obtained from a fresh specimen which had never been allowed to dry before examination and which was maintained in an atmosphere of 98 per cent relative humidity during exposure to the X-ray beam.

In order to determine how widespread crystalline alginates may be as a constituent of brown algae, we have examined a number of species spread over various orders. As shown in Table 1, the great majority of these plants yield a diagram containing reflexions which may be referred to calcium alginate, with intensities relative to those of the cellulose reflexions varying presumably according to the content and degree of crystallinity of the alginate. Most of the plants were collected during the summer from various localities along the coast of Britain, at a time when the alginate content is known to be minimal. It should, however, be noted that the members of the Laminariales and the Fucales, normally so rich in alginates as to be used commercially, are the plants yielding the strongest alginate diagram.

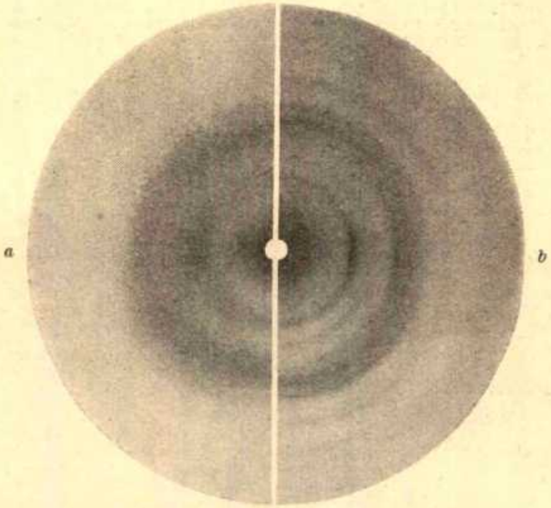

Fig. 1. X-ray diagrams of air-dried *Himanthalia elongata* stipe. Stipe axis vertical, *a*, rinsed with water; *b*, washed with hot 2 per cent hydrochloric acid

The treatment usually applied in the fractionation of wall polysaccharides (hot water for 12 h followed by chlorination for 4 h, to produce the so-called holocellulose) does not as a rule change the diagram of the material though the cellulose reflexions are enhanced since the background scatter is reduced. Considerable amounts of alginic acid are nevertheless

extracted both by the water and by chlorination as revealed by paper partition chromatography of the acid hydrolysates. The holocellulose still reacts to dilute acid as did the original material and the effect is again reversible. As an example we illustrate in Fig. 3 the relevant X-ray diagrams of *Chorda*. Extraction of the alginates from the holocellulose of *Chorda*, or of any of the plants listed in Table 1, using the standard method[11], gives a residue with an X-ray diagram of cellulose only (Fig. 4*d*), and acidification of the extract invariably gives a precipitate which yields again the X-ray diagram of alginic acid (Fig. 4*c*). Strangely enough, the alginic acid recovered from extracts of previously untreated plants yields a whole range of new diagrams different in detail among the species even though with a strong family resemblance. In attempting to resolve this apparent paradox, the nature of the alginates removed by water and by chlorination is clearly of critical importance.

The alginic acids recoverable from the water extract and the chlorite extract (exemplified here with *Himanthalia* receptacles) yield two different X-ray diagrams (Figs. 4*a* and *b*) which may be compared with Fig. 4*c*, the classic alginic acid diagram. If, for the moment, we consider the material yielding the diagrams in Figs. 4*a* and *c* as two different pure substances, then the material giving the diagram of Fig. 4*b* could be interpreted as a mixture of them. This has been verified by showing that, when equal amounts of the two putative pure substances are mixed as powders, then the X-ray diagram of the mixture is indistinguishable from that presented in Fig. 4*b*. When, however, the mixture is dissolved as sodium alginate and the alginic acid is reprecipitated, the precipitate now gives a diagram in which only the inner strong ring of Fig. 4*c* can be clearly recognized. Only after a brief heating in water, or dilute hydrochloric acid, at 90° is the diagram shown in Fig. 4*b* regained. Mixtures of the two compounds when precipitated from solution therefore tend to give a diagram which is essentially that of Fig. 4*c*.

All our many different X-ray diagrams of alginic acid extracted from fresh plants can be explained if the materials yielding them are mixtures, in various proportions, of two compounds which individually yield the diagrams represented by Figs. 4*a* and *c*. Since the diagram illustrated in Fig. 4*c* (and Fig. 1*b*) is closely similar to that regarded as standard for alginic acid and referred to polymannuronic acid, with spacings very near to those listed by Warwicker[12] and to those calculable from the unit cell of Astbury[4], then it seems reasonable to assume that the material giving our second diagram, illustrated in Fig. 4*a*, should be polyguluronic acid, the second major component of alginic acid. Paper partition chromatography of the hydrolysates of our alginate fractions by the methods of Fischer and Dörfel[13] do not, however, confirm this view. It does verify the fractioning we believe we have achieved but, while the material of Fig. 4*b* gives spots approximately equal in size and density indicating the presence of two uronic acids, the material of Fig. 4*a* gives a prominent spot for mannuronic acid, with only weak indications of the presence of guluronic acid, and that of Fig. 4*c* yields guluronic acid with only a little mannuronic

X-ray diagrams of pellets of *Himanthalia elongata* materials, air-dried. *a*, Alginic acid extracted by hot water; *b*, alginic acid extracted by chlorination of water-extracted material; *c*, alginic acid extracted with sodium carbonate solutions from halocellulose; *d*, residue after complete extraction of alginic acid (cellulose)

acid. Chromatographic separation of the lactones of these three alginic acid fractions reveals, in addition, the presence in all of them of very small amounts of glucuronic acid, which in the chromatograms of the uronic acids runs with the guluronic acid.

We are aware that a quantitative interpretation of these chromatograms must be approached with caution since the considerable losses of uronic acid which occur during hydrolysis may not necessarily be proportional to the concentrations of the various polyuronic acids initially present. There seems, nevertheless, no doubt that the diagram up to now accepted as that of poly-*d*-mannuronic acid is actually that of poly-*l*-guluronic acid. As a further check on this point a commercial preparation of alginic acid giving a mixed X-ray diagram like Fig. 4*b* was fractioned by the method of Haug[14]. According to Haug, the sodium salt of polymannuronic acid is preferentially precipitated from a 0·3 per cent solution of sodium alginate by mixing it in equal volume with a saturated solution of potassium chloride and standing for 1 h. We find that the alginic acid of such a precipitate, which must be polymannuronic acid, gives a diagram like that illustrated in Fig. 4*a*.

We are faced, therefore, with a situation in which a known substance, polymannuronic acid, has a hitherto unrecognized X-ray diagram and a known X-ray diagram refers to an hitherto unrecognized crystalline substance, polyguluronic acid. This confusion is clearly associated with the fact that, in mixtures, crystallization of polyguluronic acid tends to suppress that of polymannuronic acid. The interplanar spacings of these two acids, as we now conceive them, are listed in Table 2 together with those of the cellulose typical of brown algae.

The crystalline alginate found in untreated plants persists as a rule in the holocellulose in which the only polyuronic acid detected is polyguluronic acid. The naturally occurring crystalline alginate must therefore be a salt of polyguluronic acid with multivalent cations. This could not have been decided by X-ray analysis alone since the calcium salts of polymannuronic acid and polyguluronic acid (and indeed of polygalacturonic acid) give diagrams which are very much alike.

The question remains of the location of the polyuronic acids in the plant; are they preferentially in the wall, are they rather in the intercellular mucilage, which in the central tissue (medulla) of the fleshy weeds of the Laminariales and the Fucales is often extensive, or are they, separately or together, spread between the two? The evidence in the literature concerning both *Laminaria* and *Fucus*, based on staining reactions and taking into account the maceration of the tissues when sections are treated with sodium carbonate, is that none[9] or only minor amounts[15] of alginic acid occur in the cell wall, the bulk of it being situated in the intercellular mucilage (regarded[9] as highly swollen primary walls). If this is so, then it is difficult to understand why the cell walls swell appreciably during extraction with sodium carbonate. Our evidence is that the cell walls also contain alginic acid. This evidence comes from several sources.

When two contact X-ray microradiographs are compared of transverse sections of a *Laminaria* stipe, one treated with acid only and one with acid followed by copper acetate solution to form the copper salt of alginic acid, it is very clear that not only the mucilage but also the cell wall is very much more opaque to X-rays in the latter case than in the former. Further, when one of the above copper-treated sections is ashed on a microscope slide, the section, now in the form of a spodogram, appears unchanged under a light microscope, the cell wall being still distinct. Under these conditions a section which has been merely washed in acid leaves no residue. Since suspensions of material from which alginic acid has been removed retain only small amounts of cations, it seems reasonable to assume that the metallic ions were in either case attached to the polyuronic acids in the material and that their distribution therefore parallels that of alginic acid. Finally, thick sections of stipes, or small fragments of fronds, tend to macerate when treated with hot water and sodium chlorite, yet the resulting holocellulose, which must in the main be cell wall material, still contains appreciable amounts of alginic acid as already emphasized. This gives us a pointer toward the relative distribution of polymannuronic acid and polyguluronic acid since the polymannuronic acid is almost quantitatively removed from the material by the treatment. By and large, therefore, polymannuronic acid may be characteristic of the intercellular material, and polyguluronic acid of the wall, at least in the more complex brown algae. This concept is supported by an electron microscope examination of one particular species, *Chorda filum*, the results of which will be reported elsewhere.

Finally, it is of interest to look into the structural interrelationships of polyguluronic acid and cellulose in the walls. The X-ray diagrams of *Chorda* are particularly revealing. According to Pringsheim[16] *Chorda* is unique among the brown algae in that the walls of the cortical cells show spiral striations and spirally oriented slit pits with a strong resemblance to the condition found in conifer tracheids. The X-ray diagram of a flattened bundle of carefully aligned pieces of cortex gives a four-point diagram of cellulose as do some tracheids[17] and fibres[18], confirming the expected similarity of structure between the cells of plants with such remote relationships. The only important differences are that in the *Chorda* diagram the cellulose shows uniplanar orientation, so that the arc at 6·1 Å is faint or missing when the X-ray beam passes normally through the flattened bundle, and that a clear alginate diagram is superposed on that of the cellulose. This is evident in the holocellulose both before (Fig. 3*a*) and after (Fig. 3*b*) washing in dilute mineral acid. The arcs referring to the alginate (Fig. 3*a*) or alginic acid, specifically polyguluronic acid (Fig. 3*b*), diffuse in the former, are aligned with those of the cellulose, showing that the molecular chains of the alginate lie in identically the same helical arrangement as do those of the cellulose. This is not the first time that the polyuronides have been found crystalline and oriented in cell walls, for Roelofsen and Kreger[19] showed some years ago that the pectic compounds in the collenchyma cell walls of *Petasites* are (weakly) crystalline and with marked axial orientation. We have not, however, observed specific orientation either of cellulose or alginate in any other brown alga. We do nevertheless commonly find that the molecular chains of cellulose and alginate lie flat in the wall, parallel to wall surface, so that X-ray diagrams with the beam parallel to wall surface show pseudo-orientation of both, and Figs. 1 and 2*a* are examples of diagrams demonstrating this point.

It is quite obvious that there are here many problems still awaiting solution, including those associated with the quantitative relationships between the polyuronic acids in these plants and with the crystal structure both of polymannuronic and of polyguluronic acid. We intend to continue work along these lines.

We thank Dr. W. Eifion Jones of the Marine Biology Station, Menai Bridge, Anglesey, and the Directors and Staff of the Scottish Marine Biological Association, Marine Station, Millport, and of the Marine Biological Station, Port Erin, Isle of Man, for their help in providing us with some of the algae used in this investigation. We also thank Alginate Industries, Ltd., Walter House, Bedford Street, London, for a sample of commercial alginate.

DIRECTIONAL EFFECTS OF ALKALI METAL IONS ON ADENOSINE TRIPHOSPHATE HYDROLYSIS IN ERYTHROCYTE GHOSTS

By DR. R. WHITTAM

Department of Biochemistry, University of Oxford

ONE of the basic questions in the field of active transport is how the energy of adenosine triphosphate (ATP) is utilized to move ions against concentration gradients. In the analogous problem of muscular contraction, the contractile element is an adenosine triphosphatase, and it is therefore significant that nerve membranes have been shown to contain adenosine triphosphatases which are stimulated by sodium plus potassium and affected by substances that influence transport of sodium and potassium[1]. Similar enzymes are present in many disrupted cells and tissues, and in the presence of sodium plus potassium they are inhibited by glycosides, such as ouabain, which inhibit active ion movements in intact cells[2].

In applying results from suspensions of enzymes to intact cells, regard must be paid to the loss of the different ionic compositions normally found on the two sides of the membrane, for perhaps the most characteristic feature of transport of sodium and potassium by cells derives from this uneven ionic distribution. Thus, membranes select potassium for inward movement from a solution rich in sodium, and sodium for outward movement from an intracellular fluid rich in potassium; these unidirectional ion movements show that membranes are spatially asymmetrical in their affinity for these ions. This asymmetry is preserved in work with reconstituted erythrocyte ghosts, which allow measurements of adenosine triphosphatase activity to be made with different ionic concentrations in ghosts and medium. It has been shown that sodium stimulates from inside and potassium from outside, an effect of one ion being seen only in the presence of the other ion on the opposite side of the membrane[3,4]. Sodium and potassium therefore stimulate intracellular ATP hydrolysis synergically even though they are spatially separated by the membrane; furthermore, they stimulate at the sides of the membrane from which they are transported either inwards (potassium) or outwards (sodium). ATP hydrolysis catalysed by erythrocyte membranes has now been measured in ghosts containing various alkali metal ions in order to study further the dependence of enzymatic activity on the location of the activating cations.

ATP and one of the alkali metal chlorides were introduced into ghosts of human erythrocytes, and a low permeability was regained by allowing the membranes to be reconstituted after hæmolysis[5]. Ghosts containing one of the cations, lithium, sodium, potassium, rubidium or cæsium, were washed in saline media with a variety of ionic compositions, thus allowing the cation composition of ghosts and medium to be varied independently. The suspensions of ghosts (about 0·2 ml. packed ghosts/ml.) were incubated for 1 h at 37° in the presence and absence of ouabain (0·1 mM), and the liberation of orthophosphate from ATP was measured[3].

To find the effect of the internal cation, ghosts were incubated in a sodium–saline medium either potassium-free or containing 10 mM potassium.

The results in Table 1 show that in potassium-free medium, the rate of liberation of orthophosphate (0·99–1·46 µmoles/ml. packed ghosts/h) and the decrease caused by ouabain (0·44–0·61 µmoles/ml. packed ghosts/h) were largely unaffected by the kind of internal alkali metal. In contrast, in medium containing 10 mM potassium, more orthophosphate (in µmoles/ml. packed ghosts/h) was produced than in potassium-free medium in ghosts loaded with lithium (1·99) or sodium (2·32), although in ghosts containing potassium (1·67), rubidium (1·23) or cæsium (1·10) the orthophosphate production was not significantly increased. In the presence of 10 mM potassium in the medium, the part of the orthophosphate production sensitive to ouabain was also greater with lithium (1·44) or sodium (1·61) than with potassium (0·87), rubidium (0·75) or cæsium (0·71) as the predominant internal cation. Rubidium and cæsium therefore qualitatively resemble internal potassium in not stimulating ATP hydrolysis. Internal lithium, however, is like sodium in stimulating ATP hydrolysis when 10 mM potassium was present in the medium. The synergic stimulation due to internal lithium and external potassium was inhibited by ouabain in the same way as that due to internal sodium and external potassium.

The influence of alkali metal ions in the medium was investigated by examining their effect on ATP hydrolysis in ghosts loaded with sodium which were incubated in sodium media containing 10, 38, and 75 mM of lithium, potassium, rubidium or cæsium in place of an equivalent amount of sodium. Control incubations were made in sodium medium not containing other alkali metals. Fig. 1 shows that an increase in the rate of orthophosphate production above the controls was found in the presence of each of the ions, lithium, potassium, rubidium and cæsium, the percentage increases with concentrations of 75 mM being 66 for lithium, 84 for potassium, 53 for rubidium and 65 for cæsium. Although lithium, rubidium and cæsium were not so effective as potassium, they none the less caused a significant stimulation of ATP hydrolysis. Ouabain abolished the increased adenosine triphosphatase activity due to external lithium, potassium, rubidium and cæsium (Fig. 1) just as it did the increased activity due to internal lithium and sodium (Table 1). The replacement of external potassium by rubidium and cæsium is not surprising, for these ions are pumped into human erythrocytes like potassium[6,7], but the stimulation by external lithium is unexpected because lithium does not appear to be actively transported[7]. The finding of stimulation, however, suggests that lithium can replace external potassium as well as internal sodium.

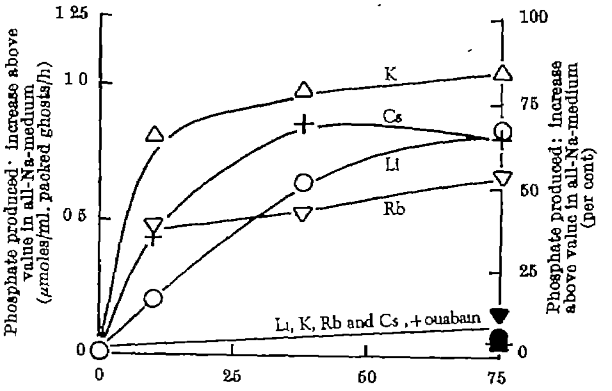

Fig. 1. Stimulation of the membrane adenosine triphosphatase by ions in the medium. A hæmolysate was made by adding 1 vol. of erythrocytes which had been previously washed with 0·15 M choline chloride, to 5 volumes of a solution of 4 mM sodium ATP and 4 mM $MgCl_2$. Sufficient 3 M NaCl was added to restore iso-osmolarity, the hæmolysate was incubated for 30 min at 37° and the ghosts were sedimented by centrifugation. They were washed once in a medium containing 150 mM NaCl, 2 mM $MgCl_2$ and 10 mM *tris* buffer, *p*H 7·6, and then suspended in otherwise similar media containing various concentrations of lithium, potassium, rubidium and cæsium, with sodium making up the alkali-metal ion concentration to 150 mM. After incubation for 1 h at 37° in the presence and absence of 0·1 mM ouabain, orthophosphate was estimated, and the graph shows the extra orthophosphate liberated in ghosts suspended in media containing lithium, potassium, rubidium or cæsium compared with that in ghosts in medium containing sodium as the only alkali metal ion (1·24 ± 0·08 (24) µmoles orthophosphate/ml. packed ghosts/h)

Table 1. THE SYNERGIC STIMULATION OF THE MEMBRANE ADENOSINE TRIPHOSPHATASE BY INTERNAL LITHIUM OR SODIUM AND EXTERNAL POTASSIUM

Orthophosphate produced from ATP (µmoles/ml. packed ghosts/h)

Alkali metal ion in ghosts	K-free medium		10 mM K in medium	
	Control	Decrease in presence of ouabain	Control	Decrease in presence of ouabain
Li	1·11 ± 0·07 (12)	0·61 ± 0·11 (6)	1·99 ± 0·18 (11)	1·44 ± 0·11 (10)
Na	1·24 ± 0·08 (24)	0·59 ± 0·07 (15)	2·32 ± 0·18 (18)	1·61 ± 0·09 (14)
K	1·46 (3)	0·61 (3)	1·67 ± 0·12 (8)	0·87 ± 0·10 (8)
Rb	1·25 (4)	0·60 (2)	1·23 (4)	0·75 (4)
Cs	0·99 (3)	0·44 (1)	1·10 (4)	0·71 (4)

A hæmolysate was made by adding 1 volume of erythrocytes to 5 volumes of a solution of 4 mM sodium ATP and 4 mM $MgCl_2$. Solutions (3 M) of either LiCl, NaCl, KCl, RbCl or CsCl were then added to restore iso-osmolarity. After 30-min incubation at 37°, the ghosts were centrifuged, washed in medium containing 150 mM NaCl, 2 mM $MgCl_2$ and 10 mM *tris*, *p*H 7·6 and suspended in the same medium. In one lot of suspension, M KCl was added to give a final concentration of 10 mM. The suspensions were incubated for 1 h in the presence and absence of 0·1 mM ouabain, and orthophosphate then estimated. *S.E.* are given and the numbers of observations are in parentheses.

In order to test this possibility, ghosts containing either sodium or lithium were incubated in a saline medium containing 150 mM lithium, either potassium-free or containing 10 mM potassium, to see whether addition of external potassium would still stimulate in all lithium medium as it does in all sodium medium. After incubation in potassium-free lithium medium, as much orthophosphate was produced in ghosts containing lithium (2·27) as in sodium ghosts (2·28), and the addition of 10 mM potassium to the medium did not cause a significant increase either with lithium (2·50) or sodium (2·47) ghosts. Further, the part of the rate inhibited by ouabain was about the same for lithium (1·15 and 1·40) and sodium (1·39 and 1·46) ghosts, both in the absence and presence of 10 mM potassium respectively. This result shows first, that the addition of 10 mM potassium in lithium medium did not further stimulate adenosine triphosphatase activity, proving that 150 mM lithium in the medium alone stimulated, secondly, that the same enzymatic activity was observed with sodium and lithium ghosts, and thirdly, that the ouabain-sensitive adenosine triphophatase activity was roughly the same in each condition. It thus appears that internal sodium and lithium stimulate adenosine triphosphatase synergically with external lithium, and that lithium is unlike the other alkali metals in stimulating from both sides of the erythrocyte membrane.

These results show that stimulation of the ouabain-sensitive ATP hydrolysis by alkali metal ions is synergic, and that the stimulation depends on the location of the cations. Thus, internal lithium and sodium stimulate but not internal potassium, rubidium and cæsium; external lithium, potassium, rubidium and cæsium stimulate but not external sodium. The striking fact that the enzymatic stimulation depends on the location of the stimulating alkali metal and that it is inhibited by ouabain, supports the suggestion that the ouabain-sensitive ATP hydrolysis is linked to the movements of the ions across the membrane[1-4]. If such a kind of asymmetrically stimulated ATP hydrolysis is indeed obligatory for active sodium and potassium movements, then unidirectional ion movements could be regarded as steric effects associated with an enzymatic reaction. The details of the possible chemical changes cannot be pursued further until the enzyme or enzymes responsible here have been purified, because the hydrolysis could equally well be due to the action of a phosphokinase and a phosphatase as to a single adenosine triphosphatase[8,9].

Whatever the detailed nature of the reaction, the finding of asymmetrical directional effects of alkali metal ions on intracellular ATP hydrolysis by membranes seems to be of some general significance with regard to the control of metabolic-rates. The rates of glycolysis and respiration are partly determined by the concentration of intracellular ADP, which is controlled in turn by the rates of the reactions hydrolysing ATP[10], one of which is the ouabain-sensitive adenosine triphosphatase of the cell membrane. Active transport by its requirement for ATP would appear to be one of the factors regulating the ADP concentration and hence to exert a feed-back control of the metabolic rates. Indeed, evidence with brain and kidney cortex suggests that some 40 per cent of the energy from respiration is utilized for active sodium and potassium transport[11]. It therefore seems that directional effects of ions regulate the rate of ATP hydrolysis by the endergonic process of active transport and that the latter exerts a feed-back control on the rate of the supply of energy from cell metabolism.

CHARACTERIZATION OF LIPOAMINO-ACIDS AS O-AMINO-ACID ESTERS OF PHOSPHATIDYL-GLYCEROL

By DR. MARJORIE G. MACFARLANE

Lister Institute of Preventive Medicine, London, S.W.1

THE formation of lipoamino-acid complexes has been reported in a number of preparations from tissues and micro-organisms, for example, hen oviduct mince[1,2], *Penicillium chrysogenum*[3], ascites tumour cells[4], liver slices[5], protoplasts of *Bacillus megaterium*[6,7]. In general, this type of complex has been demonstrated after the addition of a radioactive amino-acid to the cellular preparation, in a medium supporting metabolism, by the measurement of radioactivity in a crude or purified fraction extracted with lipid solvents and the subsequent recovery of the unchanged amino-acid after hydrolysis of the lipid fraction. Control experiments with killed preparations or with addition of the amino-acid to the lipid extract showed that the complex formation was not an artefact. Several amino-acids have been shown separately to form such complexes, and it has been suggested from various experimental findings, such as the metabolic lability and the sensitivity to chloramphenicol, that the complexes are concerned in protein synthesis[2,3,7].

Although in one sense therefore the existence of lipoamino-acids is well documented, their chemical constitution has not been elucidated, apart from the facts that the complexes are usually found in the phospholipid fraction and that the amino-acid can be recovered after acid or alkaline hydrolysis. On the other hand, the ready formation of artefacts has been emphasized[8], and investigations of lipids of cells[9,10] and micro-organisms[11] have not shown unequivocally the presence of lipoamino-acids, as distinct from lipo-peptides, proteolipids, etc.; in particular, the phospholipid fraction of the protoplast membrane of a strain of *B. megaterium*[12] and of *Micrococcus lysodeikticus*[13] were virtually free from nitrogen; in the latter organism[14] and in *Staphylococcus aureus*[15] the principal phospholipids isolated were diphosphatidylglycerol (cardiolipin type[16]) or monophosphatidylglycerol (G-P-G lipid).

Recently, however, it has been found that the phospholipid in a batch of *Clostridium welchii* cells was almost entirely bound to amino-acids, and evidence for the constitution of a lipoamino-acid as the *O*-amino-acid ester of phosphatidylglycerol is here presented.

A batch of *Cl. welchii*, type *A*, was prepared by Dr. D. E. Dolby in 30 l. of a non-toxigenic peptone–glucose medium (3 per cent peptone, 0·5 per cent glucose, 0·45 per cent NaCl). The bacteria, for some reason not determined, were not satisfactorily separated by centrifugation or filtration, but settled rapidly on acidification of the medium to about pH 3; the supernatant was siphoned off, and the bacteria were washed with water three times by centrifuging. (This apparently trivial manœuvre of acidification probably accounted for the high yield of lipoamino-acids by the arrest of enzymatic processes in presence of medium.) The packed bacteria (about 40 g dry wt., 600 ml. vol.) were extracted first with 1·6 litres of methanol, and then with 1 l. chloroform/methanol, 1:1 (v/v) by stirring at 20°. The methanol extract was concentrated and the residue dissolved in the second extract, which was then washed twice with 200 ml. 0·3 per cent sodium chloride. The chloroform layer was dried with sodium sulphate, filtered and evaporated *in vacuo*; wt. 620 mg, phosphorus, 1·8 per cent; yield of lipid phosphorus about 280 μg/g dry wt. bacteria. The methyl esters of the mixed fatty acids prepared from a portion of the lipid were identified by Dr. G. M. Gray by gas chromatography as mainly those of even-numbered *n*-saturated acids from C_{10} to C_{20}, predominantly C_{14} (24 per cent) and C_{20} (30 per cent).

The remaining lipid (8·0 mg phosphorus) in light petroleum was fractionated on a column of Mallinckrodt silicic acid (12 g), from which 140 mg of lipids free from phosphorus were eluted with benzene and chloroform. The phospholipids were then eluted with increasing concentrations of methanol in chloroform, collecting 10 ml. fractions. Eluates 9–50, eluted with 2–6 per cent methanol (v/v), were refractionated on magnesium trisilicate to give Fraction *A*, about 1 mg phosphorus, tentatively identified as a mixture of phosphatidylglycerols and phosphatidic acids, and Fraction *B*, a glycolipid (12 mg sugar) giving mannose and a trace of glucose on hydrolysis. Eluates Nos. 51–57 (3·9 mg phosphorus) eluted with 10–15 per cent methanol, Nos. 78–105 (3·0 mg phosphorus), eluted with 20–40 per cent methanol, and Nos. 106–118 (0·3 mg phosphorus), eluted with 50–80 per cent methanol, were pooled as Fractions *C*, *D* and *E* respectively, on the basis of their behaviour on silicic acid paper in diisobutylketone/acetic acid/water, 40 : 20 : 3 by volumes; all the fractions showed a lipid spot approximately in the position of phosphatidylglycerol, the one from Fraction *C* being also ninhydrin-positive, while Fraction *D* showed a separate slower ninhydrin-positive spot.

Fraction *C* was soluble in ether, chloroform and ethanol, sparingly soluble in methanol and light petroleum, insoluble in acetone; atomic ratio phosphorus/amino nitrogen[17] (ethanolamine standard)/total nitrogen, 1 : 1·03 : 1·01; phosphorus 3·5 per cent on dry wt. (calc. for the *O*-alanyl ester of distearoylglycerylphosphorylglycerol phosphorus = 3·6 per cent). On mild alkaline saponification[18] in 0·1 N methanolic sodium hydroxide/chloroform (1:1 v/v) the water-soluble product gave on paper chromatography in butanol/acetic acid/water (5 : 3 : 1 by volumes) or phenol–ammonia a single phosphorus spot corresponding to glycerylphosphorylglycerol (G-P-G) and several separate ninhydrin spots, the main spot corresponding to alanine; after acid hydrolysis, the water-soluble product gave a single phosphorus spot corresponding to glycerophosphate, and on estimation of ethanolamine and serine by treatment with fluorodinitrobenzene[19] the dinitrophenol compounds appeared in the 'serine,' that is, the amino-acid fraction. On treatment of the intact lipid with periodic acid in chloroform/95 per cent acetic acid, 1 : 1 (v/v) at 20°, with batyl alcohol as standard, only 0·1 mole of formaldehyde per mole phosphorus was produced compared with one mole for a sample of phosphatidylglycerol[14]. On thin-layer silicic acid plates developed with chloroform/methanol/water, 85 : 16 : 2, the lipid was resolved into four conjoined phosphorus spots, one very prominent, and corresponding ninhydrin spots, with a fifth ninhydrin spot visible (cf. Hunter and Goodsall[7].)

Fraction *D* was less soluble than Fraction *C* except in chloroform; the ratio phosphorus/amino nitrogen/total nitrogen was 1 : 1·1 : 2·1; phosphorus 3·4 per cent on dry wt. It was resolved similarly into four conjoined slower-moving spots on a thin-layer plate and after saponification gave on paper several ninhydrin spots distinct from those of Fraction *C*, the position of the two main spots approximating to those of lysine and ornithine. Tests for hexosamines were negative.

These facts indicated that Fraction *C* and Fraction *D* consisted of a series of *O*-amino-acid esters of phosphatidylglycerol of the general structure I, in which the ester linkage is arbitrarily assigned to the α^1 carbon of the unacylated glycerol. It was presumed that this linkage, like that of the alanyl ester in teichoic acids[20], would be very labile to alkali. Confirmation of the structure was sought by identifying the products of alkaline digestion, by the examination of infra-red spectra and by the preparation of dinitrophenyl (DNP) lipids.

$$CH_2O.OCR_1.CHO.OCR_2.CH_2O.P{:}O(OH).CH_2O.$$

(I)

R_1 and R_2 = fatty acid residues, R_3 = amino-acid residue

After shaking an ethereal solution of Fraction *C* briefly with cold 0·1 N aqueous hydrochloric acid, the phosphorus and nitrogen were recovered in the ether phase; but on treatment of the lipid with aqueous alkali, followed by acidification and extraction with ether, the nitrogen became water-soluble, the phosphorus remained ether-soluble and, concomitantly with the release of the amino-acid, the lipid became oxidizable by periodic acid with formation of formaldehyde. A slower hydrolysis of the fatty acid residues and possibly of the phosphoric di-ester linkages also occurred, and in time all the phosphorus became water-soluble. It will be seen from the course of some alkaline digestions (Table 1) that in the ether-soluble lipid the ratio of formaldehyde produced on oxidation to the total phosphorus was at the best about 0·75–0·8; a selective decomposition could presumably be achieved enzymatically.

Table 1. DECOMPOSITION OF PHOSPHATIDYLGLYCEROL AMINO-ACID ESTERS IN ALKALI

Exp.	Treatment	Time	Ether phase (μmoles) P	Amino-N	H.CHO*

		30 min	7 4	0 6	5 60

* Formed on oxidation with 0·04 M periodic acid in chloroform—95 per cent acetic acid; estimated colorimetrically with chromotropic acid.

The infra-red spectra in chloroform of Fraction *C* and *D* differ from that of a sample of phosphatidylglycerol isolated from *M. lysodeikticus*[14] (Fig. 1) in the regions 3,100, 2,100 and 1,550 cm^{-1}, indicative of amino-acids, and in the region 1,000–1,120 cm^{-1} (primary and secondary alcohols); the data are not sufficient to assign the free hydroxyl group, especially as migration may have occurred on the silicic acid column.

The DNP derivatives of Fractions *C* and *D* were formed[21] by treating the lipid (4 μmoles) in 2·0 ml. benzene with about 20 μmoles fluorodinitrobenzene and 140 μmoles triethylamine at 30° for 2 h. After evaporation of the solvent, the product was applied in chloroform along the starting line of a thin-layer silicic acid plate which was developed in chloroform.

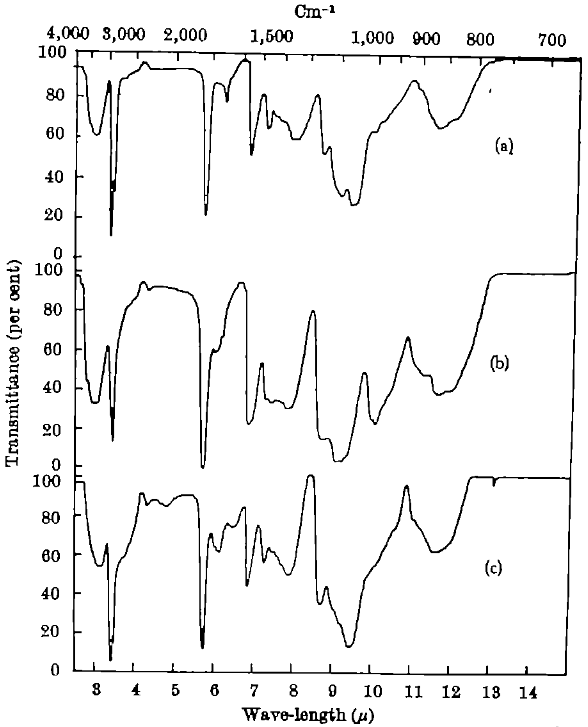

Fig. 1. Infra-red spectra on Perkin–Elmer Infracord 137. Sodium chloride cells, path-length 0·5 mm. Lipids dissolved in chloroform (*a*) phosphatidylglycerol, *M. lysodeikticus*, (*b*) diphosphatidylglycerol, ox heart; (*c*) amino-acid compound, *Cl. welchii*, Fraction *D*

The excess reagent ran with the solvent, and the yellow band at the origin was scraped off and eluted with 10 per cent methanol in chloroform. Fraction *C* DNP-lipid contained 90 per cent of the original phosphorus; ratio phosphorus/nitrogen, 1 : 2·9; λ_{max} in ethanol 342 mμ; ε(calc. on phosphorus content) $16{\cdot}7 \times 10^3$. The DNP-lipid from Fraction *D* contained 86 per cent of the original phosphorus; ratio phosphorus/nitrogen, 1 : 3·7; λ_{max} 345 mμ; ε, $24{\cdot}4 \times 10^3$ (cf. DNP-kephalin[11], λ_{max} 345 mμ, ε, $15{\cdot}5 \times 10^3$). On shaking a chloroform solution of the DNP-lipid with 2 per cent potassium carbonate solution at 20° the colour remained in the organic phase, but after warming the alkaline mixture for a few minutes the colour passed into the aqueous phase and was only re-extracted into chloroform after acidification; there is therefore little doubt that the amino-acid ester bond was intact in the DNP compounds isolated. Attempts to resolve the DNP-lipids into separate components were not successful.

The amino-acids present in the *Cl. welchii* lipids were examined by Dr. Elizabeth Work. The main acid found in Fraction *C* was alanine, and in Fraction *D* alanine, glutamic, aspartate, lysine and possibly arginine or histidine were present. No diaminopimelic acid was found.

A phospholipid fraction from *Staphylococcus aureus*, previously reported[15] as phosphatidylglycerol mixed with a nitrogenous component, was found on re-examination to contain about 60 per cent of amino-acid esters. The earlier failure[14] to find these esters in *M. lysodeikticus* was possibly due to their enzymatic decomposition during washing of the bacteria or protoplasts.

The chemical and chromatographic properties of the amino-acid esters of phosphatidylglycerol are consistent with those of the lipoamino-acids described by Hendler[1] and by Hunter and Goodsall[7], and it seems probable that their formation is a general phenomenon. The existence of phosphatidylglycerol was first recognized by Benson and Maruo[22] in plant lipids; it has also been identified in mammalian lipids[23]. In *M. lysodeikticus* most of the phospholipid of the cell is present in the protoplast membrane, either as phosphatidylglycerol or diphosphatidylglycerol; in mammalian tissues diphosphatidylglycerol is concentrated in mitochondria[24,25]. Both compounds show a rapid uptake of phosphorus-32 in metabolic conditions[23,26,27]; the route of biosynthesis is not known.

The identification of lipoamino-acids as defined compounds of a metabolically active phospholipid present in cell membranes offers some support for the suggestions[2,3,7] that they play some part in transport and, directly or indirectly, in the synthesis of protein; the incorporation of amino-acids into protein by cell fractions by a mechanism distinguishable, by the effect of chloramphenicol or fractionation procedures, from the amino acyl–ATP activating systems has been demonstrated[28,29]. It seems possible that the 'incorporation factor' for the assimilation of amino-acids by bacterial preparations, which can be derived from glycerol[30], might be concerned in such a mechanism through the intervention of a cytidinediphosphate-diglyceride[31].

I wish to thank Dr. Elizabeth Work, Dr. D. E. Dolby and Dr. G. M. Gray for their help, and Mrs. M. Bricknell for technical assistance. This work was supported by the British Empire Cancer Campaign.

AN EXPERIMENTAL EVALUATION OF THE ASSOCIATION OF PREGNANCY AND ACUTE LEUKÆMIA

By Dr. GEORGE H. GASS

Department of Physiology, Southern Illinois University, Carbondale

AND

ROBERT T. JARRETT

Stritch School of Medicine, Chicago

THE problem of leukæmia associated with pregnancy has been observed clinically by many investigators in human beings, but has been ignored experimentally except by Burchenal[1], who concerned himself with the problems of leukæmic transmission from the mother to the fœtus via the placenta in mice.

Although the clinical cases are rather isolated, there are several conclusions that have been made by the clinician which seem to be substantiated by a review of the literature. The presence of a placental barrier to the leukæmic factor is well established by the experimental works of Burchenal[1], and through the autopsies and observations made by a number of investigators[2–8]. The facts that no leukæmic mother has delivered a *leukæmic child and that* several cases of congenital leukæmia have been delivered by non-leukæmic mothers[3,12] greatly substantiate this view.

It is felt that leukæmic women do not conceive easily, due to poor physical condition[6], and to the presence of anæmia and amenorrhœa that naturally accompanies the disease, and not due to the actual deleterious involvement of the reproductive system[6]. Although there may be infiltration of the reproductive system[2,10–12], it does not seem to have any great inhibitory effect on conception as evidenced by the occurrence of women who do not have amenorrhœa and who become pregnant some months after contracting leukæmia[2–5,10,13,15], and by the occurrence of the multipara cases[2,8,9,16].

The effect of pregnancy on the course of leukæmia is one of controversy. Many clinicians feel that pregnancy causes exacerbation of the disease[13,15], while *others feel that there is little or no change* when pregnancy and leukæmia are associated[2,5,7,8,10–12,14,16]. Even a third idea is postulated by Gillim[9] that pregnancy may even have an ameliorating effect on the course of leukæmia. With these conflicting ideas in mind we have set out to study experimentally the effect of pregnancy on the course of acute myeloid leukæmia.

The animals used in this study were *C57 Bl/6J* male and female mice. The male mice were used for the transplantable tumour colony and for control animals. The females were used for controls and as the experimental subjects. The tumour used was myeloid leukæmia *C*1498, which is transmissible into the *C*57 black mouse.

In order to maintain a constant supply of transplantable tumour material, a cyclic tumour colony was established. On arrival of an initial supply of the tumour, a group of animals was inoculated (12 animals were required to initiate the cyclic transplantable colony and a number of extra inoculated animals were kept in reserve to assure that a sufficient number of animals would survive for transplanting since the average survival time for the tumour-bearing mouse is between nine and fifteen days). The cyclic colony was initiated 7 days later (the time required to allow the tumour to reach a transferable age) by killing two animals of the group of animals and inoculating two more. This procedure reoccurred each day for six days of the week. The following week the transfers were made from animals inoculated just 7 days previously. In this manner, there was tumour available on six days of the week. In addition, an auxiliary colony of 3–5 animals was carried to be used on the seventh day of the week, or in case the tumour in the cyclic colony was lost through failure of the tumour transplant.

The spleen and thymus of the tumour carriers were the organs utilized for the tumour transfer. The organs were weighed, and homogenized in a Kontes tissue grinder with sufficient 0·9 per cent sterile saline to make a 10 per cent suspension. 0·2 c.c. of the suspension was inoculated either intraperitoneally or subcutaneously into animals in which transmission of the leukæmia was desired. This was sufficient inoculum to assure 100 per cent fatality in control animals.

The results from this investigation are presented in Tables 1 and 2.

Table 1 is a presentation of the survival times of experimental animals as compared with that of the control group for those animals. Of the 41 experimental animals, 27 animals delivered viable healthy young. The remaining animals either failed to live long enough to deliver, delivered stillborn young, or on autopsy showed evidence of fœtal reabsorption. Those animals which delivered living young were inoculated during the last four days of gestation. The remainder were inoculated prior to the 14th day of gestation.

Of those animals that delivered young, either viable or non-viable, there was no indication of prematurity of birth. The normal gestation period for these mice is 19·5 days. The animals usually delivered overnight between the 19th and 20th day after conception.

The mean survival time for three sets of animals, inoculated either intraperitoneally or subcutaneously, is presented in Table 2. The mean survival time for both male and female controls, when inoculated intraperitoneally, was found to be 14·03 days and 13·10 days, respectively, with an average survival of 13·35 days. The mean survival time for those receiving subcutaneous injections was 17·86 days for the males, and 17·35 days for the females, with an average survival of 17·47 days. The mean survival time for the experimental animals was found to be 14·21 days and 17·50 days when injected via the intraperitoneal or subcutaneous route, respectively.

In an examination of the effects of pregnancy on the longevity of the mother with leukæmia, it is worth while to review the values obtained from the literature concerned with human patients.

A study of longevity forces one to divide leukæmia into acute and chronic forms. Acute leukæmia seems to follow a different course when complicated by pregnancy, or when it is contracted during pregnancy. Gillim[3] presents data that show the mean survival of 149 autopsied, leukæmic, non-pregnant adult patients to be 3·82 months[7]. This data is in close accord with work presented by Tivey[17], who found the mean survival in a study of 179 adults to be 3·3 months. The average value for the 328 patients would then be a mean survival of 3·54 months. From our review of the literature, it is found that the mean survival of those pregnant patients who have acute leukæmia is 5·54 months. This is a 36 per cent increase in longevity and would indicate that pregnancy is having an ameliorating effect on these leukæmic patients.

A comparison of the results as presented in Table 1 shows a close relationship between the survival time of the experimental animal and its control group. There is a variation (± 0–3·5 days) between the survival time of the experimental animal and its control group (except for those inoculated on the 18th day of gestation) which can be expected, since the animals usually die during the six-day period following the initial onset of death in a given group of inoculated animals due to individual vigour and resistance to disease.

By cursory examination of Table 1, it would seem that the animals inoculated during the last four days of gestation have a longer survival-rate of leukæmia. Closer examination shows that the controls for these animals lived a correspondingly longer time, thus indicating a variation in virulence of the inoculant. This is to be expected and is the reason for comparing each group with its control.

Table 1. RESULTS OF THE EFFECT OF PREGNANCY ON EXPERIMENTAL MYELOID LEUKÆMIA

Day of gestation represented	Survival time of experimental animals after inoculation (average)	Survival time of male controls after inoculation (average)	Survival time of female controls after inoculation (average)	Results of young
4 days prior*	23 (1)	15·5 (2)	20·7 (3)	Stillborn
0–8	12·0 (5)	13·2 (4)	12·2 (34)	Reabsorption or undelivered
8	16·0 (2)	16·0 (5)	14·6 (5)	Stillborn or undelivered
9	11·5 (2)	11·5 (2)	12·0 (5)	Undelivered
12	12·0 (1)	14·0 (2)		Stillborn
13	9·0 (1)	12·0 (2)		Stillborn
14	11·0 (1)		12·8 (6)	Living
15	12·0 (1)		17·0 (4)	Living
16	14·5 (6)	18·0 (4)	16·6 (19)	Stillborn (one case) all others living
17	15·7 (4)	18·0 (4)	17·0 (8)	Living
18	12·7 (3)†	18·0 (4)		Stillborn (one case) all others living
19	14·7 (7)	12·5 (2)	15·9 (29)	Living
20	17·0 (6)		61·1 (21)	Living‡

The number in the bracket represents the number of animals averaged in that survival time.

* Prior to conception.

† A fourth animal appeared to be in good health two months following inoculation. Blood samples inoculated in three animals subcutaneously and two animals intraperitoneally. All animals died of myeloid leukæmia, including mother.

‡ The young were delivered before inoculation of the maternal animal.

Table 2. SUMMARY OF RESULTS

No. of animals	Route of injection	Group	Mean survival time after inoculation (days)	Average survival time of male and female (days)
31	i.p.	Male controls	14·03	13·35
84	i.p.	Female controls	13·10	
19	i.p.	Experimental	14·21	
7	s.c.	Male controls	17·86	17·47
23	s.c.	Female controls	17·35	
19	s.c.	Experimental	17·50	

It is interesting to note that those animals which received the inoculation as late as the thirteenth day of gestation either delivered non-viable young, failed to survive sufficiently long to deliver, or showed evidence of reabsorption on autopsy. This presents a period (6–7 days) before parturition during which the tumour may have had sufficient time to cause a state of maternal nutritional deficiency which culminated in death of the fœtuses.

As shown in Table 2, the mean survival time between the experimental animals and controls is practically negligible. The survival time of the experimental animals was compared with that of the male and female controls. The averages presented show little or no difference between sexes as to duration of the disease. The mean survival time of the experimental animals inoculated intraperitoneally was 14·21 days as compared with the control survival time of 13·35 days, and those inoculated subcutaneously show a mean survival time for the experimental animals of 17·50 days as compared with the control value of 17·47 days. No significant difference in the mean survival of the two groups is shown either in those inoculated intraperitoneally or subcutaneously. Thus it would seem that the presence of pregnancy during the course of leukæmia has little or no effect on the duration of the disease in *C*57 black mice.

The findings of the first experimental work concerned with the survival time of mice, where pregnancy and leukæmia are associated, are presented. Experimental results indicate that pregnancy probably has little or no effect on the survival time of *C*57 black mice which have acute myeloid leukæmia. Experimental animals inoculated early in gestation either deliver non-viable young, fail to survive long enough to deliver, or show evidence of fœtal reabsorption. Experimental animals inoculated late in gestation (last four days) deliver viable healthy young.

ENTEROHEPATIC CIRCULATION OF UNCONJUGATED BILIRUBIN IN MAN

By Dr. A. SIGRID GILBERTSEN, IRENE BOSSENMAIER
and RUTH CARDINAL

Department of Medicine, University of Minnesota Hospitals,
Minneapolis

WHETHER or not bilirubin is reabsorbed from the intestine has been a matter of controversy for more than half a century. The failure to observe significant increase of urobilin in the fæces after tube-feeding of solutions of crystalline bilirubin to subjects with common bile duct obstruction led Fromholdt in 1912 to speculate that absorption of bilirubin had occurred[1]. Several later investigations offered direct and indirect evidence to support the concept that bilirubin is reabsorbed[2-5]. Yet other works failed entirely to support such a concept[6-10].

In accordance with earlier work[11-13] our own experiments have failed to account for tube-fed free bilirubin either as urobilinogen or bilirubin in the fæces although the similar administration of conjugated bilirubin has regularly been followed by highly significant increases of fæcal urobilinogen often approximating the amount to be anticipated. These investigations are described elsewhere in detail[14]. The disappearance of the administered free bilirubin suggested either absorption from the intestine or conversion to unrecognized substances by the fæcal flora.

The recent work of Lester, Ostrow and Schmid, using bilirubin labelled with carbon-14, clearly demonstrated that bilirubin is absorbed from the intestine of the rat and reappears in the bile[15]. Recovery of labelled bilirubin in the bile was accomplished whether labelled bilirubin was fed as the conjugated or unconjugated form, although absorption of the latter was more rapid and quantitatively greater. It was not determined whether conjugated bilirubin was absorbed as such, or whether first hydrolysed with absorption of the resulting free bilirubin. The present work was undertaken to determine whether free bilirubin is absorbed from the intestine of man.

Crystalline bilirubin labelled with nitrogen-15, 100 mg, was dissolved in 12 ml. 0·1 N sodium hydroxide and this was adjusted to pH 8·25 with 0·3 N hydrochloric acid. The bilirubin contained 1·68 atom per cent excess nitrogen-15 and was part of a large amount previously isolated from the fæces of a patient with hæmolytic jaundice who was receiving tetracycline and who was given glycine labelled with nitrogen-15. The details of this isolation were described in an earlier paper[16].

The subject of study was a 79-year-old male patient who had recently undergone cholecystectomy and choledochostomy for common duct stones and cholangitis. The latter recurred and eventually caused the patient's death. On the second post-operative day the T-tube drainage of bile was collected for 14 h as a control sample. The aforementioned solution of ^{15}N-bilirubin at pH 8·25 was administered through an inlying duodenal tube, after fluoroscopic verification of its position, on the third post-operative day. Gentle suction at 10–12 cm water pressure was applied to the T-tube for the next 48 h to divert most of the bile to the outside in accordance with the method of Layne and Bergh[17]. The bile was collected for 48 h in six samples, each of 6–12 h.

Total bilirubin content was determined on each sample by the method of Malloy and Evelyn[18]. Using the method of Ostrow, Hammaker and Schmid[19] bilirubin was crystallized from each sample for nitrogen-15 analysis. It was noted that the crystals from the final methanol were frequently accompanied by a fatty material which was readily removed by washing with petroleum ether, after which the bilirubin was recrystallized. Purity was established by determination of the nitrogen percentage (carried out in the Microanalytical Laboratory, Division of Organic Chemistry, University of Minnesota) and measure of absorptivity[20]; the nitrogen was 9·36 ± 0·3 per cent and the molar extinction coefficient 58,913. The nitrogen-15 percentages were determined in the mass spectrometer (carried out in the Department of Physics, University of Minnesota, through the courtesy of Prof. A. O. Nier) following preliminary digestion according to Rittenberg[21].

The period of collection, total bilirubin content of the corresponding sample and amount of bilirubin crystallized from each sample, are given in Table 1. Nitrogen-15 atom per cent excess of the bilirubin from each is plotted in Fig. 1. It is seen that the concentration reached a maximum within the first 18 h, then steadily diminished, although bilirubin containing nitrogen-15 in concentration greater than the control was isolated even at 48 h.

Table 1. BILIRUBIN CONTENT OF BILE AFTER INTRADUODENAL ADMINISTRATION OF NITROGEN-15 CRYSTALLINE BILIRUBIN

Bile sample No	Time period of collection after ^{15}N bilirubin feeding (h)	Bilirubin in total sample (mg)	Bilirubin crystallized for ^{15}N analysis (mg)
1	Control (14 h)	160·0	7·8
2	0–6	17·1	6·8
3	6–18	58·7	10·8
4	18–24	22·0	6·7
5	24–36	29·0	10·5
6	36–42	29·5	7·9
7	42–48	21·0	6·0

Several factors made it impossible to estimate the proportion of fed bilirubin absorbed from the intestine in the present study. Stool collections were difficult and inaccurate. *It is unlikely that the bile collection* from the T-tube was complete; some fraction of the bile probably gained access to the duodenum. Finally, the progressive hepatic dysfunction made it unlikely that the liver excreted all the absorbed bilirubin.

In the work recorded here, conclusive evidence of the enterohepatic circulation of unconjugated bilirubin in man is presented. Isotopically labelled bilirubin, fed via duodenal tube, was absorbed from the intestine and re-excreted in the bile. The

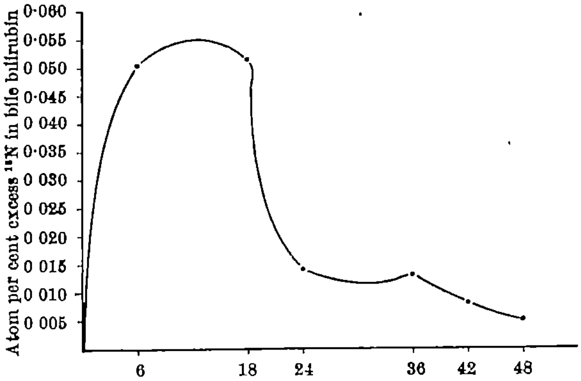

Fig. 1. Nitrogen-15 concentration in bile bilirubin after intraduodenal feeding of crystalline bilirubin labelled with nitrogen-15. The control sample described in Table 1 contained 0 000 atom per cent excess nitrogen-15

findings of Lester, Ostrow and Schmid in the rat[15] have thus been shown to be true in the human species as well. It should be noted that in the latter as well as the present investigation, the 'free' bilirubin was actually given as the sodium salt and it is not at all certain that this is formed in the intestine assuming that hydrolysis of some of the conjugated bilirubin, may occur.

The failure, in previous work, to account for tube-fed crystalline bilirubin as such or as known derivatives in the fæces of subjects with common bile duct obstruction[1,11-14] may be explained at least in part by intestinal absorption. Whether conjugated bilirubin is also absorbed as such is not yet established. In view of previous studies in this laboratory showing good recovery of tube-fed bilirubin glucuronide as urobilinogen[11], it seems unlikely that any large fraction of the conjugated bilirubin is absorbed in man, either as such or following hydrolysis.

Brief consideration should also be given to the part that intestinal absorption of bilirubin might play in explaining the frequently observed discrepancies between the amount of bilirubin formed from hæmoglobin destruction and the amounts of urobilinogen and bilirubin which can be recovered from the fæces. In order to account for these discrepancies by intestinal absorption of bilirubin, it becomes necessary to postulate that a variable fraction of the absorbed bilirubin is altered by the liver in a manner as yet unknown. We thank Prof. C. J. Watson for advice.

MUSCLE ENZYME ACTIVITY AND CHANGES IN WEIGHT IN AGEING WHITE RATS

By PROF. MORRIS ROCKSTEIN and KARL BRANDT

Department of Physiology, University of Miami School of Medicine, Miami 36, Florida

SEVERAL earlier papers reported specific age-related biochemical changes in invertebrate and mammalian structures which exhibit gross functional and anatomical changes reflecting senescence[1-3]. Moreover, such changes can be related to cessation of growth in accordance with reports by others[4,5]. This article brings up to date the findings of a long-range investigation on changes, with age, in the metabolism of organophosphorous compounds by the gastrocnemius muscle, correlated with changes in total body weight and in total muscle mass. The animals studied were male white rats from the Sprague–Dawley [(Hormone Assay Laboratories) and from the *CFN* (specific-pathogen-free (Carworth Farms)] strains, maintained at 25° C on a standardized commercial pelletized diet. Procedures used in this work have been described elsewhere[3,6].

Fig. 1 shows the results obtained for the right and left gastrocnemius muscles of animals for each of three major age-groups (based on observable changes in weight representing: (1) a juvenile period of steady growth; (2) a mature phase (400–600 days) in which the body weight remains unchanged; (3) a period of senescence during which weight loss is steady and inexorable[6]). The median values shown for the adenosine triphosphatase (ATP-ase) (magnesium-activated, *p*H 7·4) decline markedly from young to senile old age, especially during the senile period. As can be seen from both Fig. 1 and Table 1 this represents a loss in enzyme activity on a muscle mass basis of approximately 66⅔ per cent of the original enzyme activity from young, growing to old senile animals. On the other hand, changes in muscle mass on a total weight basis closely parallel those of the

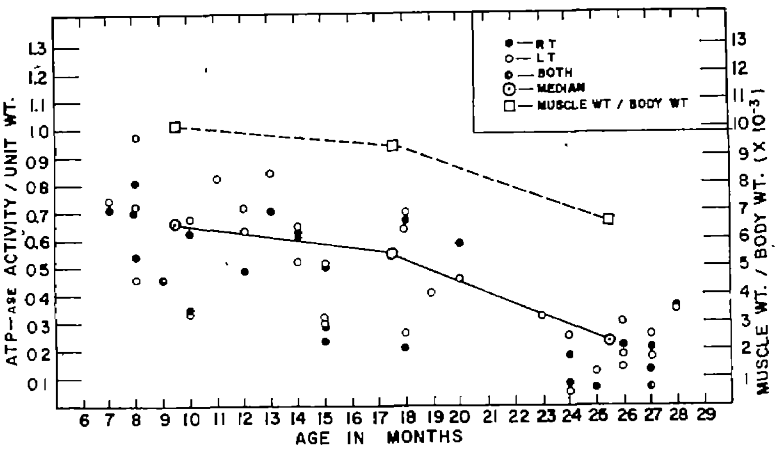

Fig. 1. Changes in magnesium-activated ATP-ase activity in the gastrocnemius muscles of ageing male Sprague–Dawley rats. Enzyme activity is expressed in µg of inorganic phosphorus released in 15 min. at 37° C per mg of fresh muscle mass

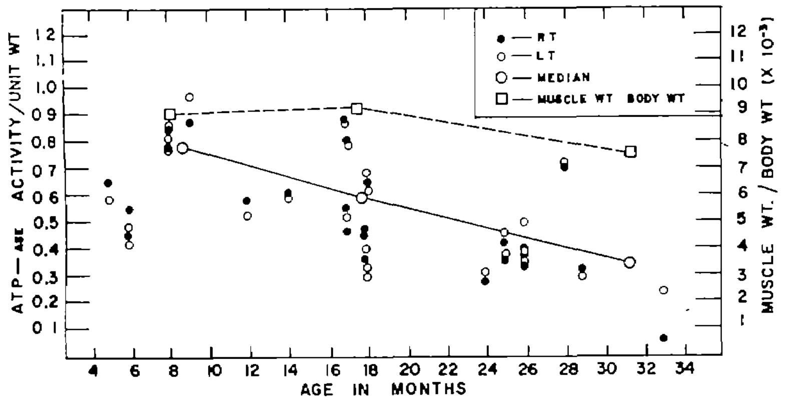

Fig. 2. Changes in magnesium-activated ATP-ase activity in the gastrocnemius muscles of male *CFN* rats. Enzyme activity is expressed in µg of inorganic phosphorus released in 15 min at 37° C, per mg of fresh muscle mass

enzyme on a muscle mass basis; this means that on a body-weight basis, enzyme activity falls even more markedly (cf. Table 1). Thus, the amount of enzyme available to move the entire body mass of an old animal is only one-fifth of that available to move that of a young growing Sprague–Dawley male white rat. It is of interest to note, in this connexion, that old male Sprague–Dawley rats exhibit a muscular dystrophy-like syndrome of the hind limbs[6,7]. The longer-lived *CFN* animals, with a much longer middle age (300–800 days) (and showing no detectable signs of muscular failure of the hind limbs at an advanced age), show only about a 50 per cent loss in enzyme activity from young to senile old age, on a muscle mass basis (Fig. 2). On a total body-weight basis, moreover, the loss in enzyme activity is only about 33⅓ per cent from young to old *CFN* animals. Comparison of Figs. 1 and 2 also shows that *CFN* animals appear to age biochemically in a more regular fashion, whereas, in the Sprague–Dawley strain, the marked decline occurs chiefly during the last third of life, and in an abrupt, precipitous fashion. Comparable results for loss in body weight of senile males in these two strains are also seen in Table 1. No significant age-related changes in the calcium-activated (actomyosin) ATP-ase were found for either strain.

Table 1. WEIGHT AND ATP-ASE ACTIVITY CHANGES IN AGEING MALE RAT SKELETAL MUSCLE

Median age (months)	Median muscle weight (g)	Median body weight (g)	Enzyme/ muscle weight	Enzyme/ body weight (× 10⁻³)
		Sprague–Dawley strain		
10	2·3	483	0·69	4 1
17	2·3	491	0·51	2 5
26	1 2	357	0·24	0 8
		CFN strain		
8	2·0	429	0 79	3 4
17	2·4	525	0·58	3·1
26	2·2	521	0·37	2·0

It is interesting that the enzyme, generally thought to be primarily concerned with contraction, itself (the myosin ATP-ase) is unaltered with age in failing skeletal muscle. Although the precise role of the magnesium-activated enzyme in the metabolism of muscle still remains a matter of speculation, the work of a number of biochemists[8,9] suggests its importance in intermediary metabolic processes intimately concerned with synthesis and dismutation of naturally occurring high-energy organic substances. Moreover, the work of Potter *et al.*[10], Moog[11] and de Villafranca[12] clearly points to a significant participation by magnesium-activated ATP-ase in the development of muscular function, that is, its activity increases with the development of the fibrillar substance in the immediately post-partum and very young chick and rat. In recent work on the giant mitochondria in the flight muscle of ageing male house flies, magnesium-activated ATP-ase activity shows a precipitous decline with the failure of flying ability in senescent male house flies, which drop is culminated in the complete loss of wings in aged males. Similar results being obtained from present work on other enzymes from such flight muscle indicate that this decline is part of a complex pattern of biochemical senescence, just as the development of flight ability is associated with the increased activity of such enzymes in post-emergent flies.

This work was completed at the New York University Medical Center, and was supported in part by grants No. *H*–2398 and *H*–3173 from the U.S. Public Health Service.

MODIFIED EQUIPMENT FOR MEASURING CHANGES IN FROZEN FISH BY LOVE'S CELL FRAGILITY METHOD

By LEONARD M. CORIS, AMEDEE J. GAUTHIER and JOHN T. R. NICKERSON

Department of Nutrition, Food Science and Technology, Massachusetts Institute of Technology, Cambridge, Mass.

IN 1958 R. M. Love described a new method for determining changes in frozen fish fillets based on the fragility of individual muscle cells when subjected to high-speed homogenization for a short time[1]. The equipment used in his later work[2-4,6] has consisted of a modified Marsh–Snow homogenizer[7]; however, the basic homogenizer is not available commercially, and it appears that much of the trouble that various other workers have experienced with the method[5,6] has been caused by the difficulty in accurately reproducing the equipment. For this reason, an investigation of the application of standard type equipment, with or without modification, to the testing of cell fragility was carried out.

A ¼-h.p. Servall Omnimixer homogenizer (1) manufactured by Ivan Sorvall, Inc., Norwalk, Connecticut, was found to be quite suitable when 50-ml. Servall cylindrical stainless-steel mixing chambers were used (6). These chambers have four 2·75-in. long grooves which start at the base of the cup and provide proper turbulence for good mixing. The complete homogenizer, including the modifications described here, is illustrated in Fig. 1.

A 0·375-in. diameter hole was drilled through the aluminium coupling adapter (2) so that the speed of the motor could be determined with a stroboscope rather than with a tuning fork, as was done by Love and Mackay[4].

The shaft tube of a 4-in. Servall rotor knife blade assembly was shortened and refitted with the bottom oilite bearing so that the overall length was 2·795 in. (4). The rotor shaft was shortened by cutting 1·180 in. off the top and 0·125 in. off the bottom and then the bottom thread was extended to the shoulder (5). A 1·375-in. long stainless-steel paddle 0·090 in. thick and 0·550 in. wide with rounded edges was made from a rod 1·812 in. long and 0·750 in. in diameter and the diameter of the top 0·437 in. of the rod was reduced to 0·375 in. (11). A socket was tapped along the axis of the top of this rod to hold the end of the rotor shaft and the top 0·125 in. of this socket was increased to the diameter of the rest of the shaft above the shoulder to allow for a true fit. The shaft tube was fitted with a close tolerance stationary chamber seal (7) which is described here.

A stainless-steel, externally threaded bushing, having an outside diameter of 0·625 in. and an inside diameter of 0·474 in. with a bottom shoulder 0·750 in. in outside diameter and 0·125 in. thick was made and fitted with a 'Teflon' washer (7*b*) placed between one 1·215-in. diameter upper and one 1·00-in. diameter lower stainless-steel washer. These washers were assembled on the bushing and secured against the shoulder by a stainless-steel lock-nut. This chamber seal was locked on to the shaft tube by means of an Allen set-screw (7*a*) passing perpendicularly through the threaded bushing. The 'Teflon' washer was made to fit very snugly against the inside wall of the mixing chamber so as to exclude air from the homogenate.

Each mixing chamber was fitted with an external, 3 in. diameter, concentric stainless-steel ring (8) by three evenly spaced, soldered stainless-steel connectors (9). A 1-pint polyethylene bottle was cut and the bottom (10) (4·0 in. deep) was attached to the outside of the bottom half of the ring by several aluminium rivets. A stationary, permanent ice and water bath was thus provided for each chamber. A cover for each ice bath was made from the upper portions of a 1-pint polyethylene bottle (3) to allow the mixing chamber to be emptied and re-used without loss of ice water. This fitted snugly around the upper half of the outside ring and the top was cut to fit just below the threaded portion of the mixing chamber. The bottom portion of each ice bath was fitted into a separate piece of 'Styrofoam' insulation (12) made by boring a cylindrical hole 3·0 in. in diameter and 3·5 in. deep into a piece of 'Styrofoam' with a 5·0 in. square cross-section and

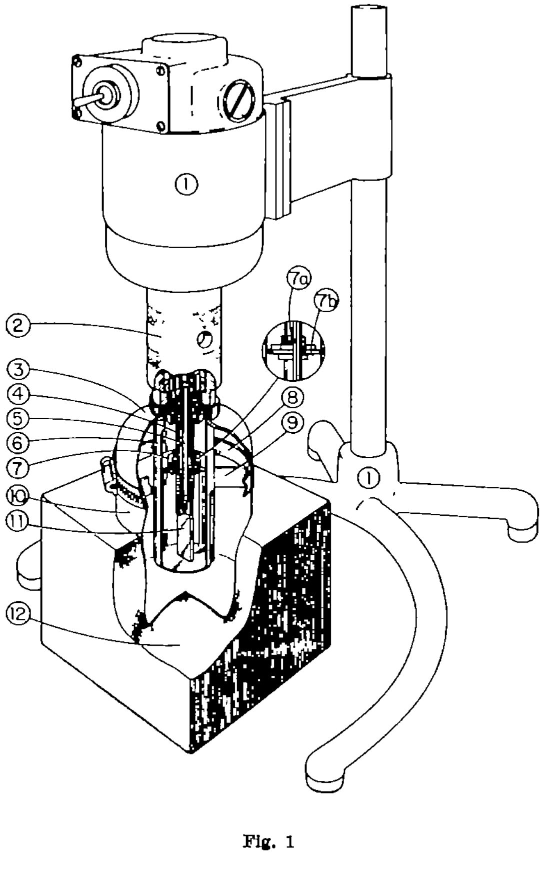

Fig. 1

a 4·0 in. depth. This insulation is capable of maintaining 32° F in the baths for 2·5 h with a room temperature of 85° F.

Only one mixing blade is necessary for several mixing chambers. The position of the chamber seal may be adjusted by means of the Allen set-screw to a minimum volume of 53·5 ml. in a Servall 50-ml. mixing chamber. With 535 ± 5 mg of fish added to this volume of the formaldehyde solution (10 mg/ml.)[6] it is possible to homogenize with an ice bath for 40 sec at 9,000 r.p.m. without beating any air into the mixture. The use of boiled, cooled distilled water for preparing the formaldehyde solution seems to help minimize the chances of foaming. The formaldehyde solution should be stored at room temperature since it has been found that refrigerated storage induces polymerization of the formaldehyde and promotes subsequent foaming of the homogenate. The latter has been confirmed by Love[5].

We wish to acknowledge Gorton's of Gloucester for their financial support of this project.

IN VITRO STIMULATION OF AMINO-ACID INCORPORATION INTO PROTEIN BY LIVER NUCLEAR RNA

By Dr. S. H. BARONDES

Clinical Endocrinology Branch, National Institute of Arthritis and Metabolic Diseases

AND

Dr. C. W. DINGMAN and Dr. M. B. SPORN

Laboratory of Neurochemistry,
National Institute of Neurological Diseases and Blindness, Bethesda, Maryland

It has been postulated that 'messenger RNA' (that is, the RNA which specifies amino-acid sequence during protein synthesis) is synthesized on a DNA template. One might, therefore, expect that significant quantities of this RNA would be found in the cell nucleus. Indeed, Sibatani *et al.*[1] have recently reported the isolation from calf thymus nuclei of an RNA fraction which has a base composition almost identical to calf thymus DNA, and which may be 'messenger RNA'. Although ribosomal RNA was at one time believed to contain the information required for genetic control of protein synthesis, studies in bacteria have tended to negate this concept[2].

The relative 'messenger activity' of nuclear and ribosomal RNA from mammals has heretofore been difficult to measure directly. Recently, however, Nirenberg and Matthaei[3] have developed a stable DNase-treated *E. coli* extract in which amino-acid incorporation into protein is stimulated by several types of RNA. This system, furthermore, synthesizes a protein resembling tobacco mosaic virus protein when tobacco mosaic virus RNA is added[4]. Since the *E. coli* extract can, in the presence of tobacco mosaic virus, make a protein similar to that made in the infected tobacco leaf, rigid species specificity of 'messenger RNA' seems to be precluded. It therefore might be assumed that the *E. coli* system would be stimulated by mammalian 'messenger RNA' and that it could be used to assay the relative 'messenger activity' of mammalian nuclear and microsomal RNA. The present report describes a comparison of the ability of rat liver nuclear, microsomal, and soluble RNA to stimulate incorporation of amino-acids into protein by this extract.

The rat liver nuclear and microsomal RNA's used in this work were isolated from adult male albino rats by a slight modification of methods which are fully described elsewhere[5]. In brief, liver nuclei were obtained by gently homogenizing the chilled, minced tissue in 0·32 M sucrose containing 0·001 M magnesium chloride and 0·0008 M potassium phosphate, *p*H 6·7–6·8. The crude nuclear sediment obtained by centrifugation of the homogenate at 600*g* for 8 min was washed three times with the homogenizing medium and then centrifuged in the Spinco *SW* 25 rotor at 50,000*g* (av.) for 2 h in 2·1 M sucrose containing 0·001 M magnesium chloride, 0·0035 M dipotassium hydrogen phosphate, and 0·0007 M ATP disodium salt, *p*H 6·7–6·8. The resulting nuclear pellet was treated with 0·10 per cent sodium lauryl sulphate in 0·001 *M* potassium phosphate, *p*H 7·0 for 5 min at room temperature and then extracted with an equal volume of redistilled phenol. The aqueous phase obtained from the phenol extraction was made 0·2 M in potassium acetate, treated twice more with 0·5 vol. of phenol, and then precipitated with 2·5 vol. of cold ethanol. The precipitated RNA was then dialysed for two days, first against 0·02 M and then against 0·005 M potassium acetate. The isolated nuclear RNA was found to be contaminated with less than 1 per cent DNA. Microsomes were obtained by first centrifuging the tissue homogenate at 34,000*g* (av.) for 8 min in the Spinco *SW* 25 rotor and then centrifuging the resulting supernatant at 105,000*g* (av.) for 60 min in the Spinco 40 rotor. RNA from the microsomal pellets was obtained in a manner identical to the isolation of RNA from nuclear pellets, except that the final aqueous phase obtained from the phenol extraction was centrifuged at 105,000*g* for 1 h to remove glycogen. The physical properties of nuclear and microsomal RNA have been found to differ markedly[5]. The use of sodium lauryl sulphate during the isolation of RNA was found to be essential for the complete liberation of nuclear RNA by phenol. The observation of Sibatani *et al.*[1] that the DNA-like RNA found in calf thymus nuclei was not liberated by conventional phenol treatment may be a consequence of excluding detergents from the extraction procedure. Recent work by Hiatt[6] appears to validate this interpretation.

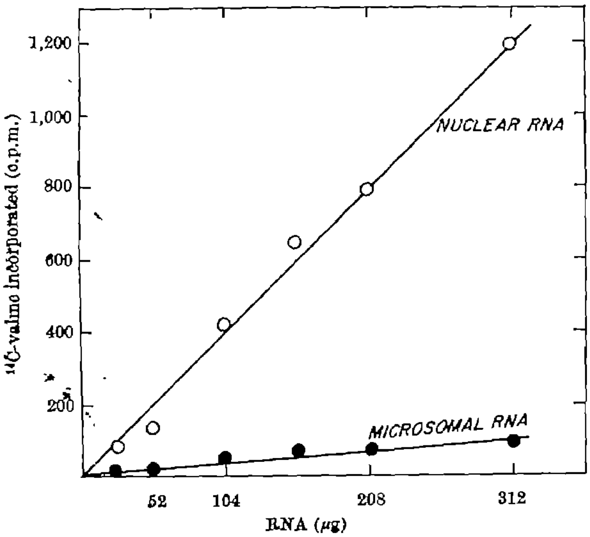

Fig. 1. Stimulation of ^{14}C-valine incorporation into protein by rat liver nuclear and microsomal RNA

Each reaction mixture contained the following in a total volume of 0·4 ml.: 40 µmoles *tris*-hydrochloric acid *p*H 7·8, 4 µmoles magnesium acetate, 20 µmoles potassium chloride, 2 4 µmoles β-mercaptoethanol, 0·4 µmoles adenosine triphosphate, 2·0 µmoles potassium phosphoenolpyruvate, 8 µgm. crystalline phosphoenolpyruvate kinase, 0·03 µmoles guanosine triphosphate, 0 02 µmoles each of 20 different L-amino-acids (as used by Nirenberg and Matthaei[2]) with 84,000 c.p.m. in L-valine, and extensively dialysed *E. coli* extract containing 1·6 mg protein and 0·5 µg crystalline DNase. No uridine triphosphate or cytidine triphosphate were added. The indicated amounts of RNA were added and the mixture was incubated for 90 min at 35° C. 10 per cent TCA was then added and the precipitate was treated by a modification of the method of Siekevitz[5]. Three tubes containing no added RNA were found to incorporate an average of 60 c.p.m. into protein and these counts were subtracted from the observed counts in the RNA-containing tubes and the resulting figures plotted

Nuclear RNA was fractionated by layering the RNA over a 4–20 per cent linear sucrose gradient containing 0·1 M potassium acetate at *p*H 6·0, and centrifuging at 25,000 r.p.m. for 16–17 h at 4° C in the Spinco *SW* 25 rotor. The optical density at 260 mµ was determined on 1-ml. fractions, collected by puncturing the tube bottom, and selected fractions were pooled and dialysed against 0·02 M potassium acetate, to remove all sucrose. These pooled RNA fractions were then concentrated by precipitation with 0·01 M magnesium acetate (final concentration) and 2·5 vol. of ethanol, and the precipitates were dried in an evacuated desiccator prior to assay of their ability to stimulate amino-acid incorporation. Rat liver cytoplasmic soluble RNA was prepared by homogenizing the tissue in 0·32 M sucrose, 0·0008 M potassium phosphate, *p*H 6·7–6·8, and centrifuging at 105,000*g* for 3 h. The RNA was then isolated from the supernatant by the procedure described here for nuclear RNA and fractionated by sucrose gradient centrifugation in a manner identical to that used for nuclear RNA. Material sedimenting between 0·5 and 9·0 $S_{20,w}$ with a peak of 5·0 *S*, was pooled for assay. Calculation of sedimentation constants was made by the method of Martin and Ames[7].

Preparation of the *E. coli* protein-synthesizing extract was carried out by the method of Nirenberg and Matthaei[2]. An 'incubated *S*-30' preparation[2], which had been dialysed against 3 changes of 0·01 M magnesium acetate, 0·06 M potassium chloride, 0·01 M *tris*-hydrochloric acid *p*H 7·8, and 0·006 M β-mercaptoethanol for a total of 18 h, was used throughout. This preparation of ribosomes and soluble materials contained crystalline Worthington DNase(3 µg/ml.), and had been pre-incubated to reduce amino-acid incorporation by the extract in the absence of exogenous 'messenger RNA'. The reaction mixtures utilized for assay of amino-acid incorporation into protein are described under Fig. 1. Supplementation with *E. coli* soluble-RNA (1 mg/ml. of reaction mixture) did not stimulate baseline incorporation by the system and did not alter the stimulation produced by liver nuclear and ribosomal RNA. Reactions were terminated by addition of 5 ml. of cold 10 per cent trichloroacetic acid, and the precipitates were washed and counted by a modification of the method of Siekevitz[5].

It may be seen in Fig. 1 that addition of liver nuclear RNA to the *E. coli* extract results in marked stimulation of ^{14}C-valine incorporation into protein. Microsomal RNA, by contrast, has only 1/10 the activity of nuclear RNA (Fig. 1). Preincubation of nuclear RNA, 800 µg/ml. with 12 µg/ml. of crystalline deoxyribonuclease for 30 min at 25° C in 0·07 M potassium acetate, *p*H 6·0, produced only slight (15 per cent) inhibition of the activity of this material. Soluble RNA prepared from rat liver cytoplasm produced no detectable stimulation of amino-acid incorporation (when 131 µg of soluble RNA were added to a 0·4-ml. reaction mixture and incubated for 60 min, 34 c.p.m. of ^{14}C-valine were incorporated, whereas the control preparation incorporated 27 c.p.m.). The time course of the reaction with nuclear RNA is shown in Fig. 2 and resembles that seen when TMV–RNA[4] and polyuridylic acid[3] are used in this system.

In an attempt to characterize further the nuclear RNA responsible for this stimulation of amino-acid incorporation, the specific activity (in terms of counts per minute of incorporated ^{14}C-valine per mg RNA) of each of four fractions obtained by zone centrifugation in a sucrose gradient was determined. These results

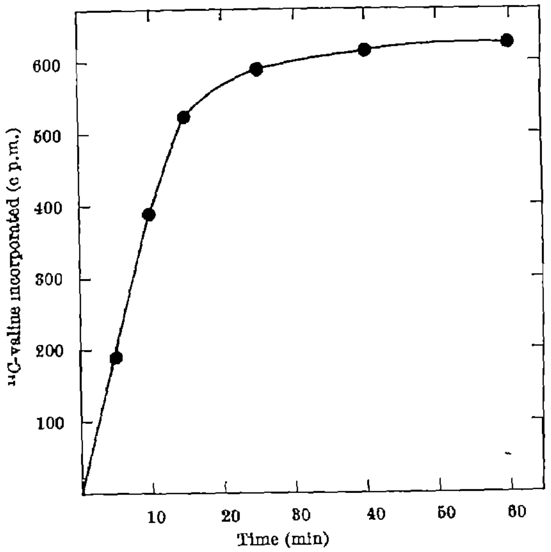

Fig. 2. Time course of stimulation of ^{14}C-valine incorporation by rat liver nuclear RNA

A reaction mixture of 2 63 ml. containing a total of 1,014 µg of rat nuclear RNA was prepared. Other reagents were present in the same concentrations as indicated under Fig 1. 0 4-ml. aliquots were removed at the indicated times and treated as indicated under Fig. 1. An identical mixture containing no added RNA was also incubated, and 0 4-ml. aliquots were removed at the same time-intervals as those indicated here and the observed c p.m. in the control samples were subtracted from the RNA containing samples before the results were plotted. After 60 min of incubation 83 c.p m. of ^{14}C-valine had been incorporated into protein in the control preparation

Table 1. STIMULATION OF AMINO-ACID INCORPORATION BY NUCLEAR RNA FRACTIONS

Fraction	$S_{20,w}$* value of fraction peak	Range of $S_{20,w}$* values pooled in each fraction	μg RNA used in assay†	Stimulation of amino-acid incorporation, c.p.m./mg RNA
1	6·4 ± 1·3‡	2·4—10 3	96	960
2	19·4 ± 0·9	16·0—24·3	45	3,300
3	32·9 ± 0 9	29·6—37·6	100	2,600
4	>40	---	125	4,900

* Calculated by the method of Martin and Ames (ref. 7).

† The assay was conducted as described under Fig. 1. Incubation was for 60 min. After the c.p.m incorporated into protein in a control tube containing no RNA were subtracted from the observed incorporation with the various RNA fractions, the data were converted to c.p.m./mg RNA. Although different amounts of the different RNA samples were used, this comparison was considered valid since stimulation with whole nuclear RNA varies linearly with the amount of RNA added throughout the range of amounts used in this experiment (Fig. 1).

‡ Values given are the mean ± the *S.D.*

are reported in Table 1, together with the sedimentation velocity constants for each fraction. It may be noted that the stimulating activity is heterogeneous with respect to sedimentation velocity, with most of the activity migrating faster than 10 *S*.

It may be concluded that RNA from mammalian liver can stimulate amino-acid incorporation into protein in an *E. coli* extract and that nuclear RNA contains far more 'messenger activity' than microsomal RNA. Although the amount of protein synthesized in the foregoing experiments was too small to characterize, one might speculate that proteins resembling mammalian proteins were synthesized. The finding of a comparatively small amount of 'messenger activity' in the microsomal RNA does not necessarily indicate that ribosomal RNA *per se* may function as 'messenger' but may be the result of contamination with 'messenger RNA', which has been shown to associate with ribosomes both *in vivo*[9] and *in vitro*[10].

We thank Dr. Marshall W. Nirenberg and Dr. Donald B. Tower for their help. Dr. Fred H. Bergmann kindly supplied the *E. coli* *s*–RNA used in these experiments.

ARTEFACTS OF ORNITHINE AND α-γ-DIAMINOBUTYRIC ACID FOUND DURING CHROMATOGRAPHIC INVESTIGATION OF RUMEN LIQUID

By DR. C. J. G. van der HORST

Oudwijk 11, Utrecht, Holland

WHILE examining amino-acids in the liquid from the rumen of cattle by means of electrophoresis at *p*H 4·5 and afterwards chromatography in the solvent system butanol–acetic acid–water (4 : 1 : 5) as shown earlier[1] a new compound, *X* (Fig. 1), was detected. From its position on the diagram it follows that *X* must have basic properties; with ninhydrin it shows a yellow colour turning to grey-blue after some time.

It was evident that *X* is formed from arginine after its conversion into ornithine. As it was not possible to get any further information about *X* with many spray reagents, the compound was isolated. After freeze-drying of the ammonia eluate on a 'Dowex 50*W*' column the amino-acids are separated by electrophoresis on cellulose powder drenched in the buffer of *p*H 4·5 as described by Montant *et al.*[2]. After freeze-drying of the aqueous eluate of *X* a separation of *X* from basic amino-acids is obtained by chromatography on 3*MM* paper in butanol–acetic acid–water. The aqueous eluate of *X* is freeze-dried, and the residue is extracted with absolute alcohol. The alcohol is evaporated and this process is repeated until no more precipitate is formed on the addition of alcohol. Finally, the brown residue is dissolved in water and treated with 'Norit'. The clear solution is freeze-dried and the residue can be purified by sublimation *in vacuo* at 80°–100° C against a surface cooled at –40° C.

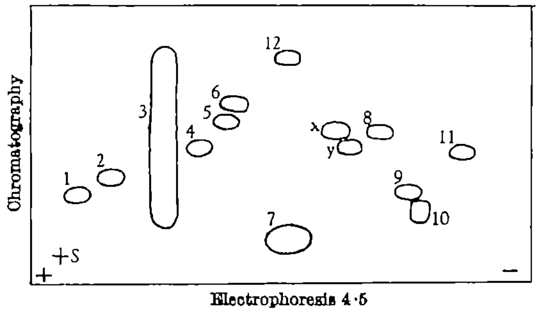

Fig. 1. 1, Aspartic acid; 2, glutamic acid; 3, neutral amino-acids; 4, β-alanine; 5, γ-aminobutyric acid; 6, δ-aminovaleric acid; 7, basic amino-acids; 8, colamine; 9, histamine; 10, cadaverine and putrescine, 11, unidentified, 12, tyramine; *X*, β-aminopiperidon, *Y*, β-aminopyrrolidon

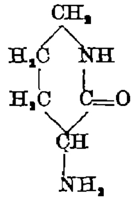
Compound *X* is a white powder which after some days turns yellowish-brown. It melts at 115°–117° C under decomposition. It is soluble in water and in alcohol. Chemical analysis (carried out by the Micro-analytical Section of the Laboratory of Organic Chemistry of the University of Amsterdam) gave the formula $C_7H_{14}N_2O_3$ and indicated the presence of one acetyl group on 2 nitrogen atoms. When *X* is gently warmed with 0·1 N sodium hydroxide it decomposes into ornithine and sodium acetate.

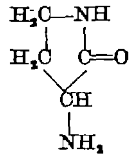
From these results it seemed probable that a cyclic compound of acetylornithine had been formed. However, when ornithine was warmed with water or with 0·1 N sodium hydroxide it appeared that ornithine was partly converted into a compound (named *Z*) which gave as *X* a yellow colour with ninhydrin. *Z* was isolated in the same way as mentioned here for *X*. It gave an infra-red spectrum completely similar to that of *X*. So *Z* is identical with *X* and must contain acetic acid. In order to avoid acetic acid, the separation of the compound formed by ornithine and ornithine itself was carried out by chromatography in propanol–ammonia. Now it was not possible to sublimate the base, but the same properties were found as in *X* in matters of electrophoresis and chromatography and decomposition by 0·1 N sodium hydroxide. So it was concluded that *Z* and *X* must be the acetic acid salt of the lactam of ornithine (β-aminopiperidon).



In 1909, E. Fischer and G. Zemplen[3] prepared β-aminopiperidon from monobenzoylornithine. They found that the melting point of the chloroplatinate was 200°–205° C under decomposition into a brown liquid. The chloroplatinate of *X* was prepared in the same way as given by E. Fischer *et al.*, and after recrystallization the melting point appeared to be 198° C and a dark brown liquid remained.

From this it is certain that ornithine, by warming with water or ammonia or 0·1 N sodium hydroxide, is partially converted into β-aminopiperidon. There seems to be a kind of equilibrium between them, because by warming β-aminopiperidon with 0·1 N sodium hydroxide the greater part of it is converted into ornithine again within 5 min. With 2 N sodium hydroxide all is converted into ornithine. The reaction may easily be followed by one-dimensional chromatography in butanol–acetic acid–water. As ornithine already is converted partially at 38° C, it is possible that in the rumen of cattle a small quantity of β-aminopiperidon is formed, but the greater part of the spot found on the diagram must certainly be attributed to decomposition of the ornithine present during the experiments.

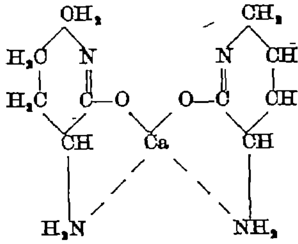
As it seemed likely that other compounds would give similar reactions, especially in cases with a possibility of formation of a five-ring, α-γ-diaminobutyric acid was examined in the same way. A yellow spot *Y* (Fig. 1) was found on the electrophoresis–chromatography diagram. *Y* was isolated in the same way as *X* with the exception of the sublimation. It reacts with 0·1 N sodium hydroxide in the same manner as *X* during formation of α-γ-diaminobutyric acid. From this it follows that *Y* must be β-aminopyrrolidon.



Just like ornithine, α-γ-diaminobutyric acid is partly converted into a cyclic form when heated with ammonia or 0·1 N sodium hydroxide.

As the compounds lysine, γ-aminobutyric acid and ε-aminocaproic acid may be present in rather large quantities in rumen liquid their reaction with ammonia has been examined. Lysine only gives a very weak spot on the chromatogram after heating with ammonia or 0·1 N sodium hydroxide, but the monoamino-acids do not form lactams in these circumstances. By gentle dry heating of these acids lactams were formed. They did not react with ninhydrin but could be detected with the reaction of Rydon *et al.*[4]. The R_F value of caprolactam is in accordance with Czerepko's results[5]. After dry heating of lysine a rather strong spot on the chromatogram was obtained in the same place where the artefact with ammonia had been found. Possibly this is also a cyclic compound.

The fact that lysine by heating with ammonia forms much smaller amounts of cyclic compounds than ornithine and α-γ-diaminobutyric acid may easily be understood as five and six rings are formed sooner than seven rings, but it is not clear why γ-aminobutyric acid does not give a cyclic compound in the same circumstances as do the diamino-acids. There are indications that the diamino-acids form chelates with calcium and magnesium; for example, when isolating *X* from rumen liquid it always contains calcium and/or magnesium. Only after sublimating *X* calcium and magnesium remain. A possible formula may be:



Of course, monoamino-acids cannot form similar chelates, but it is just a hypothesis. R_F values of the investigated compounds are given in Table 1. On electrophoresis at *p*H 1·9 the spots of β-aminopiperidon and β-aminopyrrolidon are found to the left above the spots of the corresponding amino-acids; this contrasts with electrophoresis at *p*H 4·5, when they are found on the right-hand side of the amino-acids.

Table 1. R_F VALUES OF THE COMPOUNDS INVESTIGATED

	Butanol/ acetic acid/water (4:1:5)	Propanol/ 0 2 N ammonia (3:1)
Ornithine	0·14	0·13
β-Aminopiperidon	0·38	0·58
α-γ-Diaminobutyric acid	0·12	0·26
β-Aminopyrrolidon	0·35	0·46
Lysine	0·18	-
Artefact of lysine	0·40	
γ-Aminobutyric acid	0·42	
Butyrolactam	0·70	
ε-Aminocaproic acid	0·54	
Caprolactam	0·80	

I thank Dr. A. H. Holtz for discussions and Drs. J. H. van der Maas under whose direction the infra-red spectra were obtained in the Laboratory of Analytical Chemistry of the University of Utrecht.

EGG-LAYING HABITS OF *SIMULIUM DAMNOSUM* THEOBALD AND *SIMULIUM MEDUSAEFORME* FORM *HARGREVESI* GIBBINS IN NORTHERN NIGERIA

By JOHN B. DAVIES

Sandfly Research Unit, Ministry of Health, Jamaica

DURING February–April, 1960, *Simulium damnosum* Theobald was observed ovipositing at its breeding sites on the rivers Kaduna, near Kaduna (10° 30′ N., and 07° 25′ E.); Tapa and Iku near Abuja (09° 11′ N. and 07° 11′ E.); and Mimi at Lokoja (07° 48′ N. and 06° 44′ E.). At this time, during the late dry season, the rivers concerned were very much reduced, but while they seldom dried up completely there was usually sufficient flow to support a limited population of *S. damnosum*.

The breeding site on the Tapa at the Tapa Falls near Abuja was typical of all the sites observed and will therefore be described in detail.

The river at the Tapa Falls where most observations were made was about 60 yd. wide. At this time of the year the river itself was split into three main channels which flowed swiftly between scattered boulders, rocks, clumps of grass and small thickets of *Mimosa* spp., to reach the top of the falls where it cascaded down over a much-scoured rock face, scattered with clumps of grass, to a pool some 80 ft. below. In the quarter of a mile of river above the falls only three *S. damnosum* oviposition sites were found after a careful search, and of these one was more popular than the other two. This site consisted of a 'run' of smooth, very swift, unbroken water some 10 ft. long and 6 ft. wide which flowed over the face of a rock in such a way that the surface of the water lay at about 30° with the horizontal. Below this the 'run' entered a small pool forming an area of broken foaming water.

The bank adjacent to this site was covered with large dense clumps of grass (*Chloris* spp.) overhanging the water so that a few stems and leaves trailed on the surface. It was on these trailing grass stems that large masses of eggs, sometimes exceeding ½ in. in thickness were found. Adult flies found entangled among the eggs, and later taken in the act of laying on these sites, proved to be female *S. damnosum*.

Oviposition was observed on many occasions at Abuja and usually took place about half an hour after sunset, when it was almost too dark to see and so observations were made with the aid of a torch. At Kaduna, further north, egg-laying usually began a little earlier when the Sun was just sinking below the horizon, and on one occasion, in late March, oviposition was completed half an hour before sunset. This time, however, the western horizon had been obscured by the heavy clouds of an approaching storm. This supports Crisp's[1] suggestion that the presence of an approaching storm may encourage oviposition.

As a result of these observations the stages in behaviour of *S. damnosum* prior to the act of oviposition can be described as follows:

(1) About one hour before sunset, when the humidity by the river begins to rise, adult male and gravid female flies can be observed resting on the tips of tall grasses by the river bank often as high as 6 ft. above ground-level (the inflorescence of *Chloris* spp. is a favourite site). As the light intensity decreases the females tend to move closer to the water's edge and rest lower down on grass stems and leaves. At this stage they can be easily collected by means of an aspirator if required for experimental purposes.

(2) About half an hour after sunset the females leave the foliage and are apparently attracted by the whiteness of the broken water below the laying site.

(3) From there they fly upstream about 1 in. above the surface of the water, following a zig-zag course until they reach a suitable site on which to alight. Should they fail in this after flying for about 6 ft. upstream, they will return to the broken water and approach again.

(4) On finding a suitable site (usually a grass stem or leaf trailing in the water) they will alight 1–2 in. above the water-level facing upstream, turn about, walk down the leaf to the water-level, turn about again and, facing up the leaf, will lay immediately either on the part of the leaf directly wetted by the water or in the splash zone.

(5) The eggs emerge from the abdomen in a single string which is laid down haphazardly on the substrate as the fly moves about. The eggs tend to lie side-by-side in the string, and not end-to-end as might be expected. Freshly laid eggs are white in colour changing to golden brown before morning. Once laying has started it is usually completed within a minute, while the period over which oviposition takes place lasts about half an hour.

Oviposition by up to 50 flies at a time has been observed on a single grass stalk, but since oviposition by single flies has also been observed at the same sites it is probable that mass egg-laying is due to a shortage of available sites rather than social behaviour as suggested by Muirhead-Thomson[2]. It has been observed, however, that on some days only one or two flies will lay while on other apparently similar days (in the absence of meteorological data) flies will be abundant. Marr's[3] suggestion that laying may be triggered by a drop in humidity is probably correct, although in view of Crisp's[1] observations atmospheric pressure may have some effect.

In no cases were flies observed to penetrate the surface of the water in agreement with the observations of Wanson and Henrad[4] and Marr[3]. It has been noted, however, that flies often deposit their eggs in the trough of air which forms below the water-level on the downstream side of a stalk or similar object, due to the flow lines of the water around the obstruction. Viewed from the side this could appear as if the flies were actually penetrating the surface of the water.

During oviposition, female *S. damnosum* are particularly prone to predation by the Muscids *Xenoymia oxycera* Emden which gather round the breeding sites toward evening and attack the flies as they prepare to lay[5].

While mass-laying was taking place the weight of the egg-masses caused the trailing stems to sink lower in the water, submerging the earlier eggs. It is significant, however, that the stem and egg-mass together acted as a float, keeping the eggs near the surface of the water where they would be warmed by the Sun, regardless of fluctuations in water-level.

Similar egg-laying has been observed with *S. medusaeforme* form *hargrevesi* Gibbins at the Pottery Rapids on the River Iku at Abuja between April and June 1961. In this case adult flies of both sexes could be found in large numbers in the evening on the grass bordering the rapids. On one occasion one catcher collected 72 flies in a single evening; of these about a tenth were males. The behaviour of *S. medusaeforme* was very similar to that of *S. damnosum* except that water-splashed rock surfaces formed the chief oviposition site, agreeing in general with Meeser's[6] description of laying by *S. elgonense* Gibbins (now considered as synonymous with *S. medusaeforme* form *hargrevesi*), but at Abuja the flies have never been observed to penetrate the water surface.

Adults of *S. adersi* Pomeroy have been taken from grasses along the River Mimi in the evening at Lokoja, but oviposition in this species has not been observed in Nigeria. Marr states that their laying sites are somewhat similar to those of *S. damnosum* in Ghana.

It is significant that all the *S. damnosum* and *S. medusaeforme* oviposition sites so far discovered lie upstream of any sizeable waterfall or rapid, even though comparable sites exist in the rapids or waterfalls themselves. It would seem that this is a mechanism to ensure the maximum chance of survival for the young larvæ, which once they have been swept away from their eggs, thereby stand a greater chance of finding a suitable attachment site.

TRYPTOPHAN METABOLISM IN *PSEUDOMONAS*

By DR. E. J. BEHRMAN

Department of Biological Chemistry, Harvard Medical School and the Cancer Research Institute of the New England Deaconess Hospital, Boston, Mass.

IN 1949, two groups of investigators, using the technique of sequential induction, showed the existence of two pathways for the dissimilation of tryptophan in strains of *Pseudomonas*[1-2]. Stanier and Hayaishi[3] extended and generalized these findings and indeed found that of 25 new strains examined 20 degraded tryptophan via the route discovered by Suda *et al.*[1] (through anthranilic acid (V) (Fig. 1) the aromatic pathway) and 5 via the route described by Stanier and Tsuchida[2] (through kynurenic acid (XV), the quinoline pathway). A complete scheme for the transformation of L-tryptophan (I*a*) via the aromatic pathway, pyrocatechol (VI), and β-ketoadipic acid (XIV) to Krebs cycle intermediates has been known for some years[4]. Recently, however, Dagley *et al.* have demonstrated a new type of fission of aromatic molecules[5]; an alternative metabolic branch thus exists at the level of pyrocatechol (VI). Nishizuka *et al.*[6] have worked out the metabolic steps lying between α-hydroxymuconic semialdehyde (VII) (the product of the alternative cleavage of pyrocatechol) and pyruvate and acetate (VIII–X).

There existed two major gaps in our knowledge of tryptophan metabolism in *Pseudomonas*: both were concerned with the quinoline pathway. The first of these was the pathway for D-tryptophan (I*b*) and the second, the pathway for kynurenic acid (XV). Recent work has narrowed these gaps and, further, a strain which possesses some additional enzymatic capacities has been discovered.

Transformations of Kynurenic Acid. The major experimental block in uncovering the steps in kynurenic acid metabolism arose from the difficulty of preparing cell-free extracts capable of degrading kynurenic acid (XV). Investigations revealed a requirement for DPNH in the first step (XV→XVI)[7]; it was presumably this requirement that was not easily satisfied in unsupplemented preparations. (Hayaishi *et al.*[8] have recently discovered that certain oxygenases, including the kynurenic acid hydroxylase, can be maintained in an active form by sodium borohydride reduction.) Once this difficulty was overcome, progress was rapid, especially following the identification of the next stable intermediate, 7,8-dihydroxykynurenic acid (XVI)[7,9]. Hayaishi *et al.*[10,11] have undertaken the further elucidation of this pathway the next few steps of which are shown in Fig. 1. It should be noted that the cleavage of 7,8-dihydroxykynurenic acid (XVI) is of the type discovered by Dagley *et al.*,[5] that is, α to two adjacent hydroxyl groups rather than between them.

Metabolism of D-tryptophan. Tashiro *et al.*[12] have recently clarified the pathway for D-tryptophan (I*b*) catabolism in quinoline pathway organisms. The initial hypothesis of Stanier and Tsuchida was confirmed[8]. Their later finding[13] of the non-utilization of formyl-D-kynurenine (II*b*) was probably due to impermeability. The pathway of D-tryptophan in these organisms is a separate one: D-tryptophan is converted to D-kynurenine (III*b*); the mechanism is presumably via a D-specific pyrrolase and formyl-D-kynurenine (II*b*). D-Kynurenine is then, remarkably, oxidatively deaminated; spontaneous ring closure of IV to kynurenic acid follows. It will be recalled that this same organism transaminates the L-isomer of kynurenine.

Since, of the strains known at that time, only quinoline-pathway organisms oxidized the D-isomer

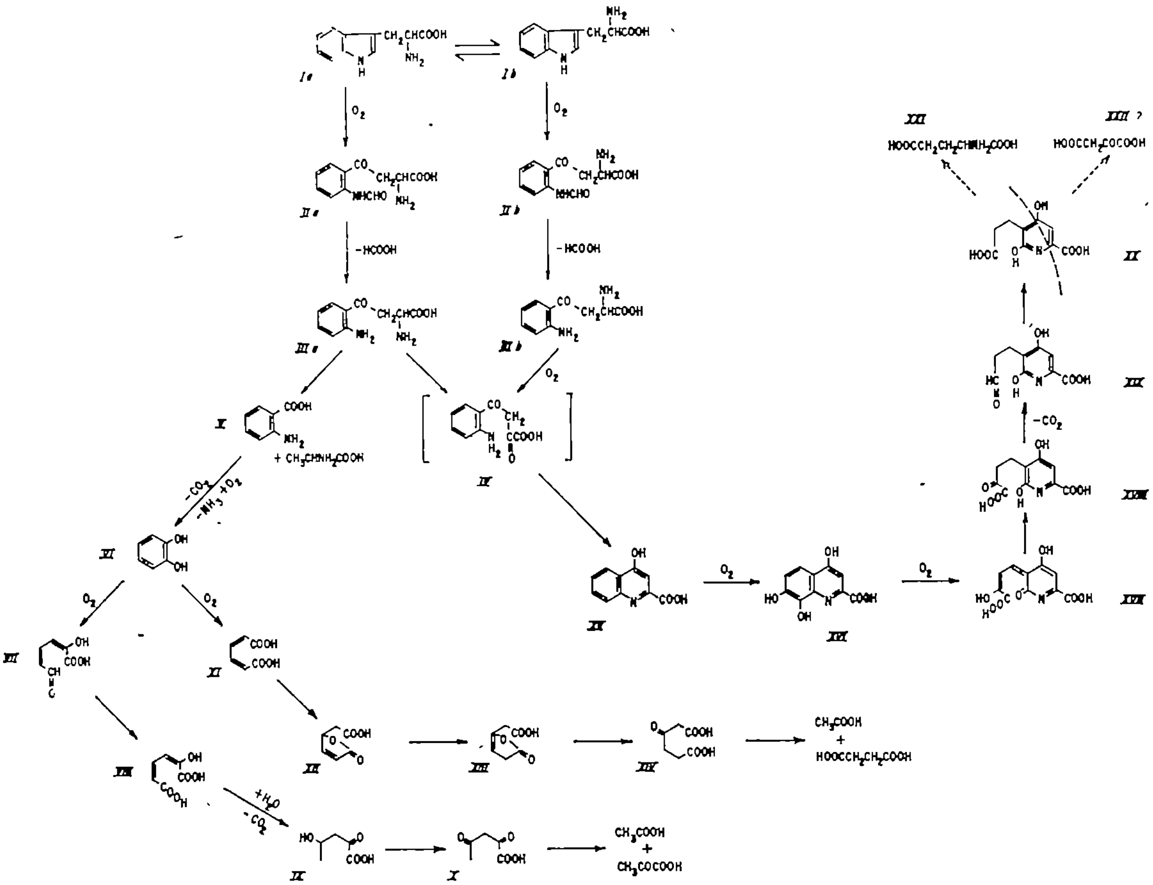

Fig. 1. Pathways of tryptophan metabolism in *Pseudomonas*

of tryptophan at a significant rate, Stanier *et al.*[13] made the suggestion that growth on D-tryptophan could be specifically used to enrich for quinoline-pathway organisms. We have isolated a strain of *Pseudomonas* (*DT*–2) (ATC,14676) from a D-tryptophan enrichment which exhibits inducible oxidative patterns typical of an aromatic-pathway organism, with this exception: the rates of oxidation of D- and L-trytophan as well as the extents of their oxidations are not dependent on the isomer of tryptophan which served as the carbon source of growth[14].

Crude cell-free extracts were prepared by alumina-grinding followed by high-speed centrifugation to remove the particulate components. Using such extracts, it was demonstrated that simple dilution or ageing allowed the stoichiometric accumulation of anthranilic acid (V) from D-tryptophan (I*b*), L-tryptophan (I*a*), or L-kynurenine (III*a*). The formation of kynurenine from either D- or L-tryptophan could be shown when extracts were treated with semicarbazide. These same extracts degrade pyrocatechol (VI) to a compound which appears to be β-ketoadipic acid (XIV), as demonstrated by its ready decarboxylation under 4-aminoantipyrine catalysis[15]. These experiments confirm the results obtained from whole-cell experiments, which suggest that the pathway for tryptophan metabolism in this organism is indeed the aromatic one.

Fig. 2 shows an experiment which demonstrates that D-kynurenine (III*b*) is not on the pathway of D-tryptophan metabolism in *DT*-2. The experiment utilized an aged, crude soluble preparation incapable of anthranilic acid oxidation. Accordingly, tryptophan and kynurenine decomposition could be observed at 310 mμ, the alkaline absorption maximum of anthranilic acid (V). Using much larger amounts of enzyme, it could be shown that D-kynurenine is slowly converted to anthranilic acid. Its rate of conversion is, however, far too slow to account for the conversion of D-tryptophan. The relative rates of conversion of L-kynurenine (III*a*), L-tryptophan (I*a*),

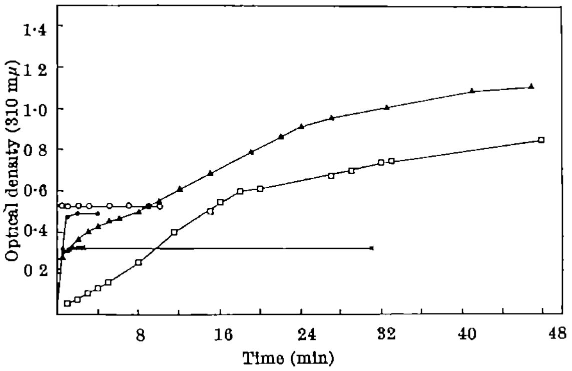

Fig. 2 Each cuvette contained· 0·1 ml. 0–40 per cent ammonium sulphate fraction (1 2 mg protein), 0 05 ml. rat liver formylase (Knox, W. E., in *Methods in Enzymology*, 2, 246, Academic Press, New York, 1955), 0·1 ml 0 02 *M* ascorbic acid (freshly neutralized), substrate additions as indicated in the figure, and 0·02 *M*, phosphate buffer *p*H 7·0 to a final volume of 3 0 ml. Temp., 26° C. ▲, 4 μmoles D-tryptophan + 0·5μ moles DL-kynurenine; □, 4μ moles D-tryptophan, ○, 0·5μ moles anthranilic acid, ●, 0·5μ moles L-kynurenine; ×, 0 5μ moles DL-kynurenine

D-trytophan (I*b*), and D-kynurenine (III*b*) to anthranilic acid (V) by the same enzyme preparation are, respectively, 100, 26, 9 and 0·1.

Anaerobic incubation of either D- or L- tryptophan with the crude soluble enzyme system resulted in the production of a racemic mixture. Ultra-violet spectrophotometry demonstrated that the tryptophan concentration at the end of the anaerobic incubation was unchanged. The extent of racemization was measured manometrically by following the oxidation of the L-isomer by moccasin venom L-amino-acid oxidase in the presence of catalase.

In later experiments, assays were performed spectrophotometrically at 328 $m\mu$, the absorption maximum of the enol-borate complex of indolyl-3-pyruvic acid produced, specifically from L-tryptophan, by L-amino-acid oxidase, the glutathione-activatable indole pyruvic acid tautomerase, and borate buffer[16,17]. No stimulation of the racemase activity could be demonstrated in crude preparations by the addition of pyridoxal phosphate, nor could any consistent stimulation be observed following ammonium sulphate precipitation and dialysis. However, the tryptophan racemase activity of eluates from DEAE-cellulose columns were consistently increased up to four-fold by the addition of pyridoxal phosphate with one-half maximal stimulation occurring at about 10^{-6} M. The purified enzyme has a *p*H optimum (*tris* buffer) at 8·3. The activity was inhibited by both 10^{-3} M hydroxylamine (90 per cent) and 10^{-3} M semicarbazide (70 per cent). No stimulation of the activity could be observed following the addition of 10^{-3} M pyridoxal, adenosine triphosphate, or glutathione.

Pyridoxal phosphate has been shown to be involved in a number of enzymatic amino-acid racemizations[18-21], while there is no evidence for its participation in other cases[22-24]; different mechanisms operate in other systems[25-27]. In the present instance, we could find no evidence for the α-keto acid, the α,β unsaturated acid, or the imino-acid as free intermediates. The most probable mechanism for tryptophan racemization is then through the azomethine formed by reaction with pyridoxal phosphate[28].

CRIMP IN COTTON

Crimp as a New Characteristic of Cotton Fibres

CRIMP is an important property of wool fibres. Artificial crimping has been produced on synthetic fibres, culminating in 'stretch' or 'high bulk' textiles. The formation of artificial crimp has been reported for jute[1]. Since the geometry of the single fibre was thus shown to be an important fibre property, it was of interest to see whether a natural crimp occurs in cotton fibres. Preliminary observations have shown the appearance of certain waves on the cotton fibres. These observations were further investigated by applying the method of defining and measuring crimp of fibres[2-4], previously developed at this Institute, to cotton.

The crimp of cotton fibres was defined by two groups of parameters, each concerning a different aspect of the fibre properties: the static parameters describe the geometrical shape of the fibre under a given load, while the dynamic parameters characterize crimp by the behaviour of the fibre on extension. The measurement of the static parameters was carried out[3,4] on a crimp meter, and that of the dynamic parameters on the Instron tester.

Two independent static parameters were used[3,4]: the crimp diameter (*D*) and the crimp ratio (*C*). The values of the static crimp parameters were determined from two enlarged perpendicular projections of each fibre, obtained from the crimp meter[4]. The dynamic parameter of crimp is the specific uncrimping energy E_i/l_i, where E_i is the uncrimping energy and l_i the length of the fibre[5] in the uncrimped state at the *i*th extension cycle. Its value is determined from the load-elongation curve recorded on the Instron tester.

Two varieties of cotton were investigated: Deltapine 15 and Acala 1517. The mean values of the static and dynamic parameters obtained for 25 single fibres from each variety, having a test length of about 15 mm, were calculated according to the method of measurement previously defined[3,4]. The measurements were carried out in a controlled air-conditioned room at 20° C and 65 per cent relative humidity. The values of the crimp parameters for the Deltapine fibres were at all loads up to 25 mg found to be considerably higher than the corresponding values for the Acala fibres.

The mean values of D and C obtained when a load of 5 mg was applied to the fibres are given in Table 1.

Table 1

	Deltapine	Acala
D (mm)	0.31 ± 0.04	0.21 ± 0.05
$C \times 100$ (per cent)	6.8 ± 0.9	6.7 ± 0.7

The difference between the mean values of the crimp diameters of the Deltapine and Acala fibres was found to be significant at a 1 per cent level of confidence. On the other hand, no difference was obtained between the crimp ratio of these two varieties, thus indicating that D alone may characterize each of the tested varieties.

The values of the specific uncrimping energies (E_i/l_i; ref. 3) were calculated for fibres subjected to continuous extensions at a velocity of 0·1 cm/min up to a load of 1 g. Five subsequent extension cycles were carried out, one immediately after the other. It was found that a considerable decrease in the value E_i/l_i occurs in the second extension cycle for both cotton varieties, whereas no further significant decrease was noted in the subsequent cycles. The values obtained from the first cycle of each fibre tested deviated from the mean much more than in subsequent cycles. Therefore it seemed reasonable to choose the specific uncrimping energy of the second cycle as a representative dynamic parameter of the given variety.

The mean values for the first and second extension cycles are given in Table 2.

Table 2

Cycle (l)	Deltapine	Acala
$\frac{E_1}{l_1}$ $\frac{\text{g cm}}{\text{cm}} \times 10^{-3}$	3.60 ± 0.94	2.42 ± 0.48
$\frac{E_2}{l_2}$ $\frac{\text{g cm}}{\text{cm}} \times 10^{-3}$	1.85 ± 0.42	0.67 ± 0.18

The difference between the values of the specific uncrimping energies for the second cycle (E_2/l_2) was found to be significant at a 2 per cent level of confidence.

On close visual observation of the single fibres, the foregoing quantitative measurements are qualitatively confirmed, and the Deltapine fibres seem to be more crimped than the Acala fibres. It is to be expected that fibres with higher crimp should be more entangled in their lot. Hence the force (P) applied when separating a fibre from the lot was measured on the Instron tester, on 50 single fibres from each variety. The mean values obtained (Table 3) were found to be in accordance with the above visual impression and the crimp parameters measured:

Table 3

	Deltapine	Acala
P (mg)	295 ± 45	180 ± 35

The results show that the static, as well as the dynamic, parameters can be used as a sensitive means for differentiation between cotton varieties. It is interesting to note that no difference was found between the mean values of the cross-sectional area and of Young's modulus for the two varieties, indicating that the crimp of cotton fibres is a property of a given variety, not necessarily related to the fineness of the fibre or its general elastic behaviour.

This work forms part of a research project being carried out at this Institute under grant No. *FG-Is-103-60*, issued by the Agricultural Research Service, United States Department of Agriculture.

Some Aspects of the Behaviour of Crimp of Cotton Fibres

In handling the fibres during ginning, baling and withdrawal from the cotton lots, different forces are applied to each fibre. These forces cause deformations to the crimp of the fibre, and it seems that the recovery of crimp depends on the extent of the deformation as well as on time. The changes of crimp occurring when different loads are applied to a fibre were therefore examined and the recovery properties of the deformations, as a function of time, were investigated.

Two varieties of cotton were investigated: Deltapine 15 and Acala 1517. The dependence of crimp on load was studied by means of two independent static parameters: The crimp diameter (D) and the crimp ratio (C). The method for defining and measuring the values of these parameters were previously evolved at this Institute[2,4].

The mean values of D and C were calculated for 25 single fibres under five states of load (w), from 5 mg up to 25 mg. A decrease of the crimp diameter (D) with the load was observed for both cotton varieties, as shown in Fig. 1. This decrease may be represented (Fig. 2) by the simple functional relationship:

$$\frac{1}{D} = aw + b$$

The values of the constants a and b obtained for the two cotton varieties are given in Table 4.

Table 4

	Deltapine	Acala
a (mm^{-1} mg^{-1})	0·30	0·45
b (mm^{-1})	1·45	2·60

The values of the crimp diameter (D) of the Deltapine fibres were found to be significantly higher than the corresponding Acala values for loads up to 20 mg.

A decrease in the crimp ratio with load was also observed, but no difference between the values for the two varieties was found to exist for the loads applied. This decrease is represented in Fig. 3.

The recovery of crimp of fibres subjected to tensile deformations was measured by the dynamic parameters. The specific uncrimping energy ($E/1$), defined[3,5] as the amount of energy necessary to uncrimp a fibre of a unit length, was used. Its values were obtained from the load-elongation curve of each fibre, recorded on the Instron tester. The immediate recovery of crimp and the retarded recovery (after 24 h of relaxation) were measured.

The immediate recovery was examined by performing five subsequent cycles of extension (up to 1 g) at a velocity of 0·1 cm/min and unloading immediately one after the other. Twenty-five fibres from each variety, having a test length of about 15 mm, were investigated. A recovery of about 50 per cent from the initial specific uncrimping energy was obtained for the Deltapine fibres during the second extension cycle. The corresponding recovery for the Acala fibres was only about 25 per cent. These recovered uncrimping energies kept their values unchanged during the subsequent cycles of both varieties.

The retarded recovery was determined by performing two immediate extension cycles and then keeping the fibres in a relaxed condition for 24 h in a controlled air-conditioned room at 20° C and 65 per cent relative humidity. After rest, two successive additional extension cycles were carried out on each fibre. It was found that after the relaxation of the fibres the specific uncrimping energies of both cotton varieties increased to about 55 per cent from their original values, thus indicating a time-dependent recovery. At the fourth extension cycle, performed immediately afterwards, the specific uncrimping energies were again reduced to about the same values as at the second cycle.

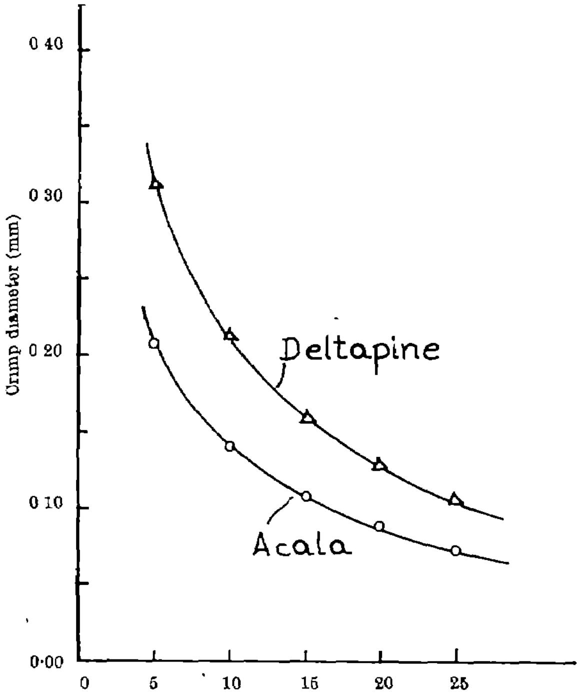

Fig. 1. Dependence of the crimp diameter (*D*) on the load (*w*)

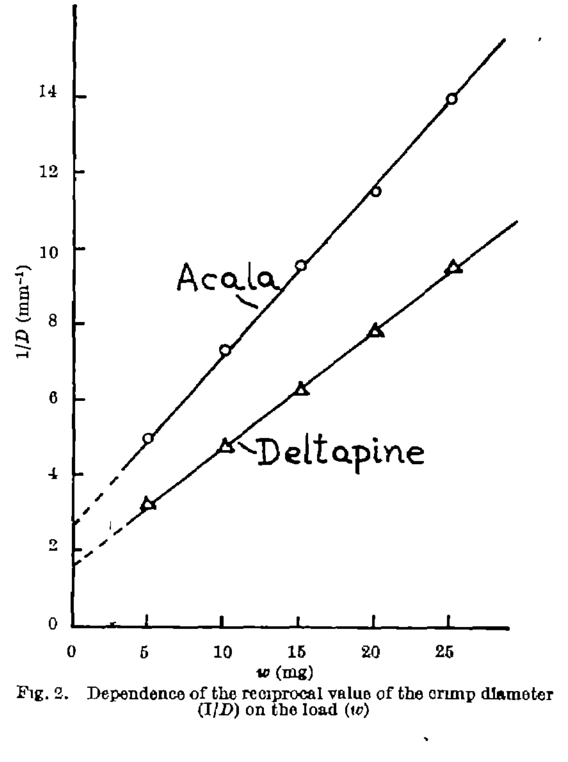

Fig. 2. Dependence of the reciprocal value of the crimp diameter (1/*D*) on the load (*w*)

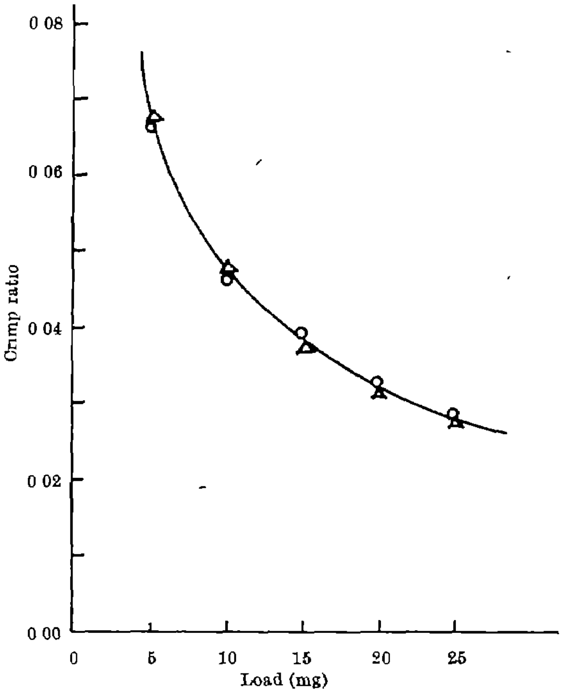

Fig. 3. Dependence of the crimp ratio (*C*) on the load (*w*) Δ, Deltapine; o, Acala

These results on the recovery of crimp show that the deformation of crimp which occurs during the extension of the fibre is composed of a reversible and an irreversible part. The reversible deformation includes an immediate elastic recovery and a retarded recovery. The immediate recovery of the specific uncrimping energies obtained at the second extension cycle keeps its value unchanged during the immediate subsequent cycles. It follows, therefore, that its value is independent of the forces applied to the fibre (up to 1 g). It appears that this stable part of the crimp of cotton is the important factor in the processing of fibres into yarns and fabrics, and affects the properties of the finished goods.

LETTERS TO THE EDITOR

COSMOLOGY

Radio Background as a Criterion for Cosmological Models

As I have recently shown[1], the number counts of extragalactic radio sources according to the latest Cambridge survey[2] imply that in an evolutionary cosmology there is a minimum rate of evolution of the power of the radio sources, which depends on the time variation assumed for the spatial density of the sources. The particular cases when the spatial density of the sources is always proportional to that of ordinary galaxies and, alternatively, to the square of that of the galaxies, were found to require a diminution of mean source power exceeding 1·4 and 0·2 per cent per 10^8 years, respectively, at the present epoch. More generally, when no definite assumption was made regarding mean source density $\bar{n}(t)$ and mean source power $\bar{P}(t)$, it was found that agreement with the Cambridge results required a minimum present rate of diminution of the product $\bar{n}(t)\bar{P}^2(t)$ equal to 5 per cent per 10^8 years. In these calculations the Hubble time T was taken to be $1{\cdot}3 \times 10^{10}$ years.

The question now arises as to how this kind of evolution affects the radio background intensity at a given frequency due to the radio sources. Since it now appears possible to isolate the contribution of the radio sources to the background from that due to the normal galaxies[3], this observational approach to the cosmological problem may prove to be a very valuable one.

To deal with this matter consider any isotropic world model whose metric, in the usual notation, is:

$$ds^2 = c^2dt^2 - \frac{R^2(t)\{dr^2 + r^2d\theta^2 + r^2 \sin^2 \theta d\varphi^2\}}{(1 + kr^2/4)^2} \quad (1)$$

Let $E(\nu,t)$ (watts ster^{-1} (c/s)$^{-1}$ parsec^{-3}) be the emissivity of space at frequency ν and epoch t due to the radio sources of spectral index x. Then the sky brightness at the observer, at frequency ν_0 and epoch t_0, will be:

$$B(\nu_0,t_0) = c\int_{t^*}^{t_0} \left\{\frac{R(t)}{R(t_0)}\right\}^{3+x} E(\nu_0,t)dt \quad (2)$$

where t^* is the earliest epoch of emission of radiation contributing to the local radio background. In the case of the simple steady state model, in which $R(t) = e^{t/T}$ (T constant) and $E(\nu,t)$ is statistically independent of t, this yields:

$$B(\nu_0,t_0) = \frac{cT\,E(\nu_0,t_0)}{3 + x}$$
$$= 0{\cdot}26\, cT\, E(\nu_0, t_0), \text{ if } x = 0{\cdot}8 \quad (3)$$

In the evolutionary models the function $E(\nu,t)$ must be related to the power and spatial density of the sources since these depend on the epoch. The different power classes of the sources may be suitably labelled according to their emissive power P_0 (watts ster^{-1} (c/s)$^{-1}$) at the observed frequency ν_0 and at the epoch of observation t_0. Then, if $\bar{P}_0$ is a suitably defined mean power of the objects (observed in a given range of flux density) at the same frequency and epoch, the emissive power of the class P_0, at frequency ν_0 but at general epoch t, may be denoted by $P(l,t)$, where $l \equiv \log_{10}(P_0/\bar{P}_0)$ and $P(l,t_0) \equiv P_0$. Suppose now that the spatial density at epoch t of objects in the power class P_0, $P_0 + dP_0$, or equivalently l, $l + dl$ is $\eta(l,t)dl$. It follows that the emissivity due to all classes, at frequency of observation ν_0 but at the general epoch of emission t, is:

$$E(\nu_0,t) = \int_{-\infty}^{\infty} \eta(l,t)P(l,t)dl \quad (4)$$

It will be sufficiently general for the purpose to assume that for a limited range of past time:

$$\eta(l,t) \propto \{R(t)\}^{-p} \quad (5)$$

for all l, where p is a disposable constant. The cases already mentioned of proportionality of radio source density to that of the galaxies, and to the square of that of the galaxies, are given by setting $p = 3$ and $p = 6$ respectively. It is then appropriate to take:

$$P(l,t) \propto \{R(t)\}^{-q} \quad (6)$$

where q is a disposable constant. Hence, for the sky brightness at the observer due to objects of spectral index x one finds:

$$B(\nu_0,t_0) = c\, E(\nu_0,t_0)\int_{t^*}^{t_0} \left\{\frac{R(t)}{R(t_0)}\right\}^{3+x-p-q} dt \quad (7)$$

To agree with the number counts p and q cannot be arbitrary, as I have stated at the outset. In fact, taking $x = 0{\cdot}8$ the following inequality must be satisfied (equation (4·9) of my earlier paper[1]):

$$p + 2q > 6{\cdot}6 \quad (8)$$

I have verified that, for the special family of models in which $R(t) = t^n$ (n constant) and $k = 0$, this condition is necessary for a rising $\log (N/N_0) - \log S$ curve[2], at least as far as the peak of the Cambridge curve ($S \simeq 6 \times 10^{-27}$ watt m^{-2}(c/s)$^{-1}$ at 178 Mc/s). Consider as a representative example the Einstein–de Sitter model in the cases $p = 3$ and $p = 6$ and take t^* to correspond to the peak of the Cambridge curve.

(1) $p = 3$, $q > 1{\cdot}8$. For $q > 1{\cdot}8$ the contribution to the sky brightness from sources in any range of flux density S must exceed that for the case $q = 1{\cdot}8$ since $N(S)$ at each S will be greater. In the case of the Einstein–de Sitter model when $q = 1{\cdot}8$ I have shown[4] that at $S = 6 \times 10^{-27}$ watt m^{-2} (c/s)$^{-1}$ the corresponding mean epoch of emission is t^* where $t^*/t_0 = 0{\cdot}11$, taking $\bar{P}_0 = 10^{26}$ watts ster^{-1} (c/s)$^{-1}$ (at 178 Mc/s) as the Cambridge[2] evidence appears to suggest. Hence, substitution of these values gives as a lower limit for $B(\nu_0,t_0)$ in the Einstein–de Sitter model when $p = 3$:

$$B(\nu_0,t_0)_{\min} = 1{\cdot}04\, cT\, E(\nu_0,t_0) \quad (9)$$

(2) $p = 6$, $q > 0{\cdot}3$. A similar calculation yields a lower limit for $B(\nu_0,t_0)$, by setting $q = 0{\cdot}3$ and again integrating up to $S = 6 \times 10^{-27}$ watt m^{-2}(c/s)$^{-1}$ where now the mean epoch t^* of emission is found to satisfy $t^*/t_0 = 0{\cdot}34$. For this case

$$B(\nu_0,t_0)_{\min} = 1{\cdot}06\, cT\, E(\nu_0,t_0) \quad (10)$$

It appears, therefore, that for two widely differing but plausible values of the source density as a function of the epoch, assuming for each case the corresponding minimum possible rate of power evolution to give a rising $\log(N/N_0) - \log S$ curve, the Einstein–de Sitter cosmology predicts much the same sky brightness due to the radio sources of spectral index 0·8. Furthermore, for the assumed value of $\bar{P}_0$ this minimum sky brightness is 4 times that expected in the steady state cosmology without minimizing. It follows that if the Cambridge estimate of the luminosity function of not too distant sources were confirmed, assuming present possible ambiguities[5,6] had been removed from it, then $E(\nu_0,t_0)$ would be known and another criterion for cosmological models would be available.

In this connexion, investigators[7] at Jodrell Bank have claimed a considerably lower value for $\bar{P}_0$ (about $2{\cdot}5 \times 10^{24}$ watts ster^{-1} (c/s)$^{-1}$) than the value assumed here on the basis of the Cambridge evidence. In this case the peak of the Cambridge $\log(N/N_0) - \log S$ curve would correspond to a much nearer point in space than hitherto believed, and therefore the contribution to the radio background from more distant sources might be of the same order as that due to the sources within the survey. However, assuming the most reasonable variations of power and density beyond the point $S = 6 \times 10^{-27}$ watt m^{-2} (c/s)$^{-1}$, calculations show that in this case, both for $p = 3$ and $p = 6$, the background intensity for the Einstein–de Sitter model can be fairly definitely restricted to lying between $0{\cdot}2\ cT\ E(\nu_0,t_0)$ and $0{\cdot}5\ cT\ E(\nu_0,t_0)$. This differs from the result (3) for the steady state model by a factor of less than 2. Therefore, if the Jodrell Bank interpretation were proved correct measurements of the radio background would be less likely to provide a useful distinction between cosmological models.

Finally, a point worth observing is that since $\bar{n}_0\bar{P}_0^{3/2}$ is a known constant obtained from the number counts ($\bar{n}_0$ being the mean number of sources locally per unit proper volume of space), then $E(\nu_0,t_0) \propto \bar{n}_0\bar{P}_0 \propto \bar{P}_0^{-\frac{1}{2}}$. Hence on the basis of the Jodrell Bank luminosity function the expected background intensity in any cosmological model would be about six times that expected on the basis of the Cambridge luminosity function.

RADIOPHYSICS

Decametric Wave-length Absorption resulting from the Nuclear Detonation of July 9, 1962

Following the high-altitude nuclear detonation on July 9 at Johnston Island there was observed a pronounced effect on the 10·006-Mc riometer data taken at the Air Force Cambridge Research Laboratories, Sagamore Hill Radio Observatory, in Hamilton, Massachusetts (lat. 42° 38′, long. 70° 49′). This riometer consisted of a Collins *R–390A–URR* receiver with a band-width of 1 kilocycle, and a dipole antenna oriented in an east–west direction.

Onset of the absorption occurred (Fig. 1) between 0403 and 0408 E.S.T. ($H + 3$ to $H + 8$ min), reached a maximum drop in signal-level of 6·9 db. at 0421 E.S.T. ($H + 21$ min), and was essentially back to normal by 0500 E.S.T.—slightly less than 1 h after the onset.

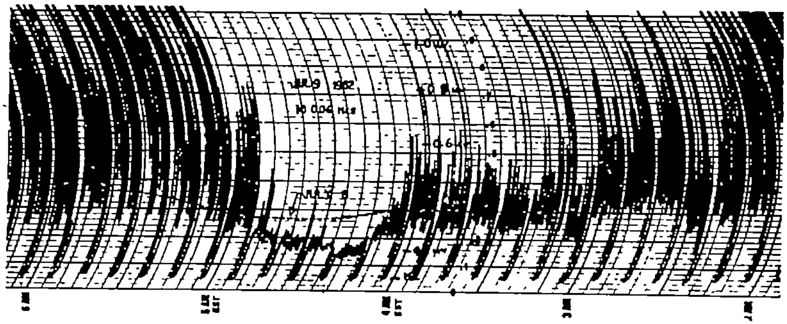

Fig. 1. 10 Megacycles absorption record of July 9, 1962, with previous day-level shown by dashed curve

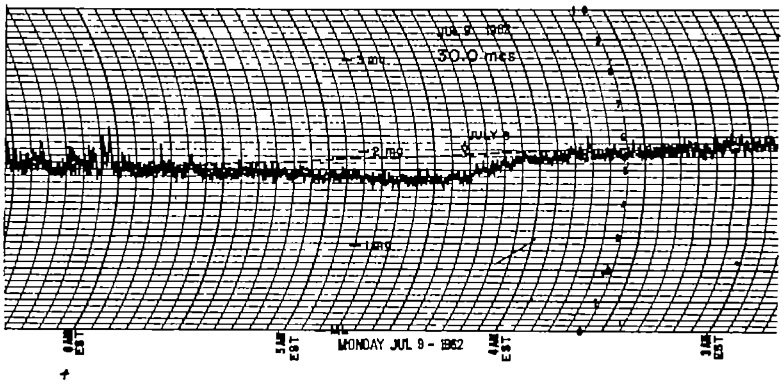

Fig. 2. 30 Megacycles absorption record of July 9, 1962, with previous day-level shown by dashed curve

Exact time of the start of the absorption was difficult to obtain as the normal sunrise effect decrease begins about this time of morning. Sunrise time for the *D*-layer altitude on July 9 occurred at about 0354 E.S.T. The plotted previous day-level (July 8) shows the normal decrease expected and, in fact, shows the largest decrease over the three days preceding the event day. On the actual day, no unusual solar activity was reported by other observatories. The decrease noted on July 9 was thus much greater than would normally have been expected.

Due to the large receptive angle of the dipole antenna, propagated signals, mainly of the teletype nature, are also recorded as part of the riometer signal. This gives uncertainty to the degree *D*-layer absorption contributes to the 6·9 db. drop in signal-level. Characteristics of the propagated signal is the increased excursion width of the recorded signal. With the increased excursion width some change in base-level occurs, but this should be small due to the fast time constants used in the receiver.

The drop-out of propagated signals during the event was pronounced. Levels shown for 0·5 h prior to 0400 E.S.T. represent the 'smallest' propagated excursions expected at this time of morning—in particular when compared with the larger excursion values obtained for the days of July 6, 7, and 8.

Sagamore Hill is situated almost 39° geomagnetically north of Johnston Island, thus any trapped particles must have passed well to the south of this Station as the sheath encircled the globe. This sheath appears to have been mainly responsible for the drop-out of the propagated signals, especially when they originated from the southern azimuths to this station.

That a true *D*-layer absorption occurred at this high a latitude is confirmed by results from a 30-Mc riometer also located at this Station. From Fig. 2 it can be seen that a similar decrease occurred at this shorter wave-length. Sunrise effect decreases are normally not observed with this equipment. The antenna used is a *yagi* pointed to the celestial-polar region of the sky—thus limiting observations to a more selective area and in the northern quadrant of azimuth. The change in db. was much less than that of the 10 Mc, as would be expected by the inverse-frequency-squared law of absorption; and may in part also be due to the beam orientation used. Maximum absorption of the 30-Mc signal was of the order of 0·5 db.

D-layer absorption occurring at this site may be the result of prompt neutrons from the burst decaying into β-particles, which were then guided into the *D*-layer via magnetic field lines[1]. These β-particles could have come in field lines some distance from the Sagamore Hill site and created a prompt absorption at that injection point. The travel time for the disturbance to reach this Station would then account for the delay time noted for the onset of absorption.

Detection of the effects of a high-altitude nuclear detonation with measurements made a large distance away from the detonation area, and well removed from the trapped radiation sheath, are well illustrated by these 10- and 30-Mc absorption observations.

GEOPHYSICS

Observation of the (0,0) Band of the ($^1\Delta_g - {}^3\Sigma_g^-$) System of Oxygen in the Day and Twilight Airglow

THE (0,1) band of the ($^1\Delta_g - {}^3\Sigma_g^-$) system of oxygen was first observed in the twilight airglow in 1958 by Vallance Jones and Harrison[1]. The (0, 0) band, although theoretically at least 10 times stronger, was not detected from the ground because of re-absorption by oxygen in the lower atmosphere.

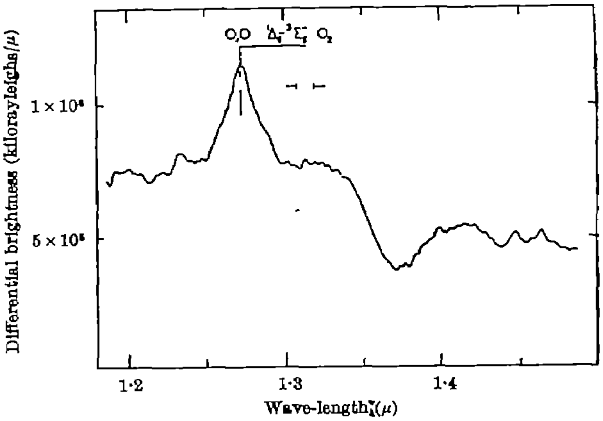

Fig. 1. Dayglow spectrum obtained from a height of 13 km at a zenith angle of 55°. The (0,0) oxygen (O_2) band is shown. The spectral slit width was 100 Å and the solar zenith distance was 40°

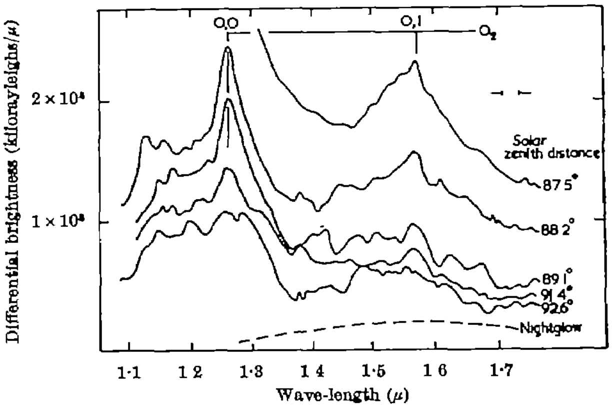

Fig. 2. Twilight airglow spectra obtained from a height of 13 km at a zenith angle of 75°. The spectral slit width was 250 Å and the solar zenith distance varied between 87·5° and 92·6°

Recently, it has become possible to make observations with a grating spectrometer flown in a *KC*–135 aircraft at a height of 13 km, and a successful observation of the (0,0) band in the day and twilight airglow has been accomplished.

Fig. 1 shows a dayglow spectrum obtained at a solar elevation angle of 50° and Fig. 2 shows a set of twilight spectra. The line of sight of the spectrometer was at 90° to the direction of the Sun in azimuth, and was at zenith angles of 55° and 75° for the dayglow and twilight spectra, respectively. The absolute brightnesses were obtained by comparison with the spectrum of a standardized low-brightness source. The (0, 0) band is present in the spectra at 1·27μ and is superimposed on a background due to scattered sunlight; in the present observations the weaker (0, 1) band was largely masked by noise.

The integrated areas of the oxygen band were measured after subtraction of the background and the total brightnesses of the oxygen band derived. These brightnesses were reduced to zenith by multiplying by cosine of the zenith angle and were corrected for molecular oxygen absorption by using the approximate value of the band extinction coefficient of 2·2 km^{-1} given by Vallance Jones and Harrison. This will give an approximate value only for the true brightness of the emission, but it is probably correct within a factor of two or three even at the large zenith angle.

Fig. 3 shows the results of the dayglow measurements obtained on April 1, 1962, at 45° N. and the twilight measurements obtained on February 4, 1962, at 20° N, plotted as a function of solar elevation angle. The dayglow intensity of the (0, 0) band is close to 10,000 kilorayleighs, which is in agreement with theoretical estimates made by Vallance Jones and Gattinger[2] in the course of their interpretation of the intensity and decay of the (0, 1) band in the twilight. Their interpretation ascribes the atmospheric emission of the $(^1\Delta_g - {}^3\Sigma_g^-)$ bands to the production of excited oxygen molecules by photodissociation of ozone. These preliminary observations also show that the twilight decay of the bands begins noticeably before sunset. This is to be expected, since the exciting solar radiation penetrates less deeply into the atmosphere as the Sun nears the horizon.

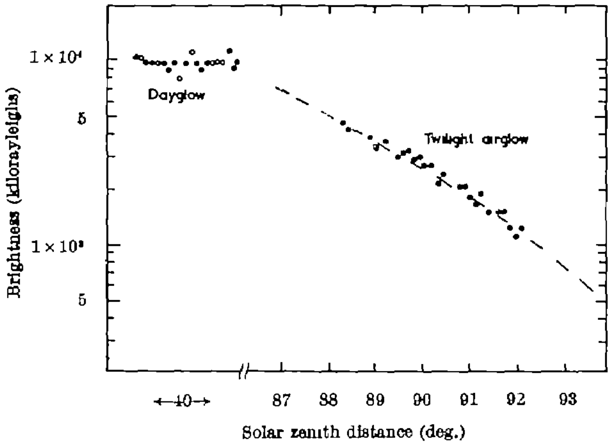

Fig. 3. The brightness of the (0,0) oxygen (O_2) airglow band as a function of solar zenith distance, as derived from Figs. 1 and 2. The brightnesses have been reduced to the zenith and corrected for absorption by atmospheric oxygen

The (0, 0) oxygen band is by far the most intense feature yet observed in the day airglow. The only other dayglow emissions detected so far are the sodium lines at 5893 Å (ref. 3) and the red lines of atomic oxygen at 6300 Å (ref. 4); both emissions have a zenith intensity of about 30 kilorayleighs.

This work was sponsored by the Geophysics Research Directorate, Air Force Division, Office of Aerospace, U.S. Air Force, under contract *AF* 19(604)-7265 with the University of Saskatchewan and also supported in part by a grant to Harvard University from the National Science Foundation. Installation of the scanning spectrometer aboard the *KC*-135 aircraft was made possible through the cooperation of Dr. G. Gassmann and Mr. T. P. Markham, of the Air Force Cambridge Research Laboratories.

PHYSICS

Elementary Particles

THERE appears to be a relation between some basic laws of physics and the numerical value of certain natural constants when dimensional units are defined in a particular way.

The velocity of light is a universal constant and it can be assigned a value of one. From the uncertainty principle of Heisenberg, the product of the standard deviation of the position of a particle and the standard deviation of the momentum of a particle equals $\hbar/2$. If the dimensional units are assigned so that the standard deviations or variances equal one, then $\hbar = 2$. The square of the electron charge (e^2) then equals twice the fine structure constant or $2a$.

Suppose $y = f(x)$, where x is a random variable of mean zero and variance one. Then $y = \exp - x^2/2$ and the area squared equals 2π. When $x = \pm\pi$ then $y = \exp - \pi^2/2$. If $\pm\pi$ equals rest mass then y corresponds to charge. These may be the parameters of the components of all particles. If similar components combine to give a mass of 2π then the Compton wavelength equals 2 since $M\lambda$ equals 4π. The charge squared should be a function of $2 \exp - \pi^2/2$. The function seems to be $2 \exp(-\pi^2/2 + 2 \exp(-\pi^2/2 + 2 \exp - \pi^2/2))$ (ref. 1).

The difficulties in locating basic particle[2] suggest $Me/e^2 = Mp/g^2 = \pi/a$, where Mp equals the proton mass and g^2 is the nuclear force constant. In this case $g^2 = 2a$ when Mp is assigned the value 2π (ref. 3). Electrons and protons are then similar combinations of stationary states of the random variable.

If rest mass has a sign then combinations of opposite sign for charge and mass will have zero rest mass and zero charge. Energy is a random variable and can take any value. The neutrino is a particle with these properties.

The important role of chance and stationary states in basic processes is evident in the quantum theory. Perhaps these basic factors can also account for the various elementary particles and the numerical values of the constants which identify them.

Dependence of the Anisotropy Axis Dispersion on Thickness of Thin Nickel-Iron-Cobalt Films

THE measurement of easy axis dispersion in thin ferromagnetic films is of interest in connexion with the explanation of their magnetic behaviour. Clow[1] has reported the variation of the dispersion of easy axis with film thickness for evaporated specimens of 82-18 per cent nickel-iron alloy in the thickness-range 50-2000 Å. In the work reported here, measurements of dispersion were made by a slightly different method on films of nickel-iron-cobalt alloy in the range 400-6000 Å in thickness.

The method of measurement used here has been described by Crowther[2] and is the low-frequency counterpart of the technique suggested by Peacock and Winsor[3]. A loop plotter, similar to the type described by Crittenden *et al.*[4], was used to observe the transverse flux pick-up when the film was switched with a 400 c.p.s. alternating field. The angle between the field and the hard axis of the film was varied until the net flux observed was equal to one-half of the maximum possible flux. The angle α_q between the field and the mean hard direction was measured. This angle was of the order of 1–4° and could be measured with an accuracy of ± 1/4°. Clearly this angle was such that when the applied field was zero, 75 per cent of the film had become magnetized in one sense along the easy axis. Measurements of α_q were made on films evaporated in a vacuum of approximately 10^{-5} mm mercury on to aluminium substrates held at an elevated temperature. Two batches of films were measured, each consisting of a series of successive evaporations from ingots of composition 80 per cent nickel–17 per cent iron–3 per cent cobalt. The difference between the two batches lay in their substrate temperature.

The substrates measured 11 cm × 8 cm and at their corners the films showed an easy axis dispersion characteristic of angle-of-incidence anisotropy[5]. Since, however, the pick-up coil of the loop plotter was of such a shape that it effectively detected flux changes only in a narrow strip across the centre of the specimen, contributions to the measurements from this source would not be expected.

Fig. 1 shows the measured variation of α_q with thickness for the two batches of specimens. It is seen to be roughly constant above about 1500 Å thickness, rising steeply as the thickness falls below that value. The difference between the curves for the two batches suggests that there may be a dependence of the dispersion on substrate temperature for thick films.

The dependence on thickness shown in Fig. 1 is so different from that reported by Clow for nickel–iron films that different mechanisms must be operating in the two cases.

To explain the dependence observed in nickel–iron films, Clow[1] has suggested that the dispersion increases with grain size, which might be expected to rise with increasing film thickness. Since the actual dependence of grain size on thickness has not been reported for either nickel–iron or nickel–iron–cobalt films, comparison on the basis of this model is impossible. However, there is some evidence[6] that the measured amplitude of dispersion is dependent on the self-demagnetizing field of the specimen, but only when this field becomes comparable to the anisotropy field. The nickel–iron specimens used by Clow were of a constant diameter of 1·5 mm (Clow, H, private communication), so that the demagnetizing field of a 2000 Å specimen was about 1 œ, compared with an anisotropy field H_k of 3 œ. The observed variation of dispersion may have been a result of the demagnetizing fields present. In the present specimens, however, the demagnetizing field of the thickest specimen was less than 0·05 œ, so that this explanation would not apply.

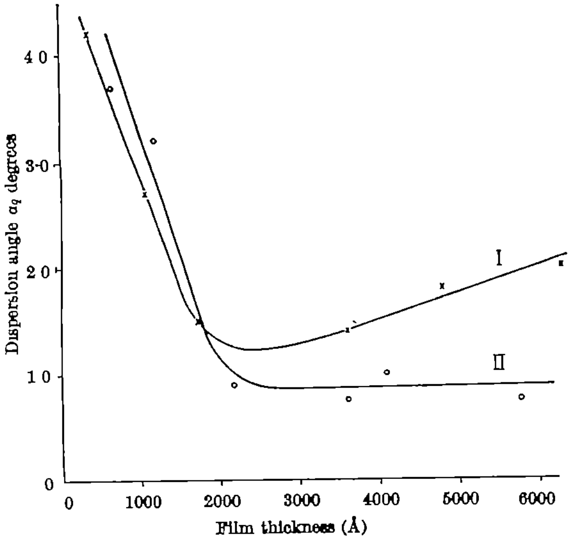

Fig. 1. Variation of dispersion angle α_q with film thickness for nickel–iron–cobalt films. I, Films with substrate temperature 350° C, H_k = 5–6 œ; II, films with substrate temperature 150° C, H_k = 10–11 œ

It has been reported that in the initial stages of growth the film consists of isolated islands of material, and that in this state the film displays super-paramagnetism[7]. The easy axes set up in this initial layer of material will probably be randomly oriented. As the film becomes thicker, the easy axes will become more closely aligned, owing to the high internal field of the ferromagnetic state. The influence of the initial layer with highly dispersed easy axis may be felt up to greater thicknesses. Such a model accounts qualitatively for the observations reported here.

I thank Mrs. J. Phillips for assistance in the preparation of the films.

Correction to the High-Pressure Scale

CALIBRATION of the pressure scale may be accomplished by determining the pressure associated with, for example, volume discontinuities of known materials, such as bismuth[1]. The question arises as to whether the pressure on the calibration material is the same as the pressure generated by a ram or a surrounding liquid or solid medium.

The calibration material may be in a container that is closed, or open at top and bottom (a sleeve). When in a closed container, it can be shown that the pressure external to the container is different, in general, from the pressure within the container[2]. Whether in a closed or open container, the stresses on the contained material are not isotropic, with average stress in the specimen different from any applied stresses.

Many calibrations of specimen materials (bismuth and cæsium, for example) have been performed with specimens in containers of materials less compressible than the specimen materials. This practice has led to measured pressures (outside the containers) higher than within.

Transition points used for calibration of the absolute pressure scale in this manner so far reported are consequently in error by amounts dependent on relative physical properties and sizes of containers and specimens. Preliminary calculations indicate these errors can be several per cent of reported pressures.

GEOCHEMISTRY

Further Isotopic Age Measurements on Rocks from North-eastern Greenland

SUBSEQUENT to the publication of our earlier communication[1] a few additional critical samples of basement rocks from north-eastern Greenland were obtained and analysed. These are given in Table 1. The rubidium–strontium determination on the potassium feldspar cogenetic with the biotite from the alkali granite (*GAA*–135) confirms the presence of an ancient basement in this region. Even this age of 2,290 ± 70 m.y. must be regarded as a minimum due to the possibility of earlier metamorphic events. Since the potassium–argon on the biotite from this rock gave an apparent isotopic age of 1,900 ± 50 m.y., it seems unlikely that the ^{87*}Sr/^{87}Rb ratio of the feldspar was affected by the Caledonian orogeny.

Table 1. ISOTOPIC AGES FROM ROCKS IN NORTH-EASTERN GREENLAND

I. Pre-Cambrian Basement

Sample No.	Rock type	Mineral	Isotopic age (m.y.)	Rb p.p.m.	Normal Sr p.p.m.	Radiogenic Sr p.p.m.	Location
GAA-135	Alkali Granite	Feldspar	Rb/Sr = 2290 ± 70	455	8·80	4·41	70° 20′ N./29° 47′ W.

II. Caledonian Infra-structural Rocks (Pre-Middle Devonian)

Sample No.	Rock type	Mineral	K/Ar Isotopic age (m.y.)	K (per cent)	^{40}Ar s.c.c./gm.	Location
GW-73*r*	Schist	Muscovite	K/Ar = 410 ± 10	6·74	$1·23 \times 10^{-4}$	73° 11′ N./27° 40′ W.
JH-146	Granodiorite	Biotite	K/Ar = 395 ± 10	7·29	$1·27 \times 10^{-4}$	73° 20′ N./26° 50′ W.

The potassium–argon ages on the muscovite from the schist (*GW*—73*R*) which was developed during the main phase of the orogeny and the biotite from the syn-orogenic granodiorite (*JH*–146) further confirm the observation that the Caledonian activity around the North Atlantic ended by 390 m.y. ago in Lower Devonian time.

CHEMISTRY

Kinetic Law in the Adjustment Period of Natta's Polymerization

THE Ziegler–Natta polymerization of α-olefines has been widely investigated by many workers mainly from the practical point of view. On the other hand, the details of the reaction mechanism are not yet clear. There are, of course, some basic investigations of the reaction by Natta *et al.*[1], one of which is considered here; that is, the kinetic behaviour of the polymerization of propylene in the initial stages (Natta's 'the adjustment period'), where the polymerization-rate, r, changes with the polymerization time, t, from the initial rate, r_0, at $t = 0$, to the stationary rate, r_∞. The phenomenon can be divided into two types, that is, the build-up type and the decay type. The decay type was observed with the ground catalysts (sizes $\leqslant 2\mu$), while the build-up type was observed with the unground ones ($1 \sim 100\mu$). Analysing the latter types of rate change, Natta *et al.* found that:

$$t_N \propto 1/P \tag{1}$$

$$\ln t_N \propto 10 \text{ kcal}/RT \tag{2}$$

where t_N is the polymerization time at which the rate equals 3/4 of the value of the stationary rate, r_∞, and P the pressure of propylene. Natta suggested that the stationary reaction corresponds to a definite particle size of the catalyst, and any other catalyst with a different particle size would alter to this definite size.

In order to compare the kinetic behaviours of the two types, I have carried out the polymerization with the active catalyst (titanium trichloride-'ARA' of Stauffer Co., Ltd.) and obtained some decay curves as shown in Fig. 1. Analysing the results, we have:

$$(r - r_\infty)/(r_0 - r_\infty) = \exp(-k_K t) \tag{3}$$

$$k_K = AP\exp(-6·5 \text{ kcal}/RT) \tag{4}$$

$$r_\infty = BP\exp(-10 \text{ kcal}/RT) \tag{5}$$

$$r_0 = CP\exp(-9·8 \text{ kcal}/RT) \tag{6}$$

where A, B, and C are the frequency factors. Here, it should be noted that the rate equation of the stationary polymerization (5) is in agreement with Natta's result, except for the value of B. My value of B is larger than that reported by Natta, which may be attributed to the large surface area of 'ARA' (about 20 m^2/g by BET method with nitrogen adsorption).

From equation (3) we have, denoting by t_K, the time at which the rate equals 4/3 of r_∞:

$$t_K = \frac{1}{k_K}\ln\frac{3(r_0 - r_\infty)}{r_\infty} = \frac{\text{const.}}{k_K} \propto \frac{1}{P} \tag{7}$$

and from equations (7) and (4):

$$\ln t_K \propto \ln\frac{1}{k_K} \propto 6·5 \text{ kcal}/RT \tag{8}$$

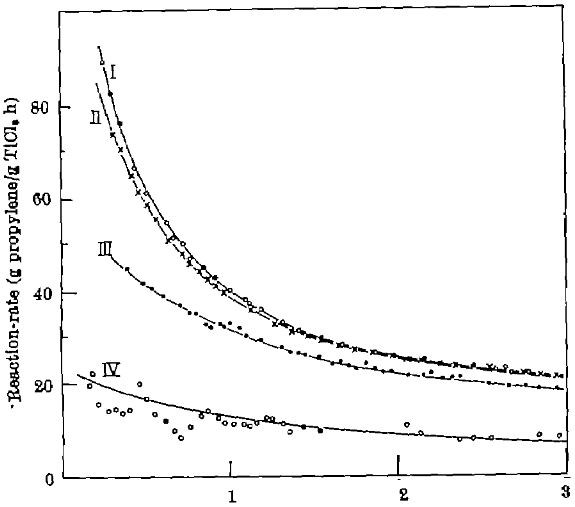

Fig. 1. Propylene polymerization-rate at different temperatures and pressures as function of polymerization time: I, 60° C, 550 mm mercury; II, 44° C, 650 mm mercury; III, 27° C, 710 mm mercury; IV, 10° C, 740 mm mercury. Other conditions are approximately the same (Ti ~ 2 g/L; Al/Ti ~ 1)

These relationships are formally the same as equations (1) and (2), respectively. In view of this, the following expression may be attributed for the curves of Natta's build-up type:

$$(r_\infty - r)/r_\infty = \exp(-k_N t) \tag{9}$$

with

$$k_N = A'P \exp(-10 \text{ kcal}/RT) \tag{10}$$

Furthermore, it should be pointed out that we have a new equation, differentiating equations (9) and (3) with respect to t, as:

$$\frac{dr}{dt} = -k(r - r_\infty) \tag{11}$$

where k is k_K or k_N.

The last equation, thus derived, is the kinetic law in the 'adjustment period' of Natta's propylene polymerization.

I thank Drs. R. J. Cvetanivić, S. Bywater, Y. Amenomiya and S. Affrossman for discussions.

Catalytic Decomposition of Cobalt (III) Hexammine Cations on the Surface of Montmorillonite

THE stability of crystalline cobalt (III) hexammine chloride up to 100° C and in solution is well known[1]. Morel[2] has proposed the use of $Co(NH_3)_6^{3+}$ for the determination of the cationic exchange capacity of clay. The fast colorimetric determination of an excess of reagent would provide an accurate routine analysis for cationic exchange capacity of clay minerals such as kaolinite and montmorillonite; this method gives results in agreement with the classical ones, but with an alumino-silicate gel (cracking catalyst) steric hindrance precludes such an agreement.

Table 1

	(a)	(b)	(c)	(d)
Montmorillonite	100	118	100	112
Cracking catalyst	118	40	—	—

Cationic exchange capacity (m.equiv./100 g oven-dried, at 105°) data obtained from ammonium acetate method (*a*), from cobalt (III) hexammine colorimetric determination (*b*), from direct Kjeldahl determination (*c*) and indirect Kjeldahl determination (*d*).

Since the infra-red data for $Co(NH_3)_6Cl_3$ have been thoroughly examined by several authors[3-5], it may be of interest to compare them with the spectra obtained for the complex cation adsorbed on a clay surface. The film technique[6] is especially suitable for this purpose and montmorillonite constitutes, from this point of view, a very good material.

When films of lyophilized or air-dried montmorillonite saturated with $Co(NH_3)_6^{3+}$ at different pH are examined, besides the spectral features belonging to the clay lattice, bands are found which may be obviously attributed to the complex.

If the same films are either outgassed under vacuum at room temperature or dried at temperatures up to 100° C, the decomposition of the complex occurs within a few minutes, resulting in a considerable transformation of the spectra. The new bands indicate that ammonia evolved is strongly adsorbed as ammonium ions. When the sample is dried under vacuum at low temperature in a cell similar to that proposed by Wagner and Hornig[7] the complex is not destroyed. Fig. 1 shows the spectra obtained under these different conditions. In a recent paper, Mortland, Fripiat, Chaussidon and Uytterhoeven[8] demonstrated the very strong affinity of acid- or base-saturated montmorillonites for gaseous ammonia, the chemisorbed species existing as ammonium ions. For base-saturated montmorillonites they explain this transformation as follows: the chemisorbed water molecules are strongly polarized by the exchangeable cations and do exist in a dissociated form. NH_3 reacts with a proton giving NH_4^+. If montmorillonite saturated by $Co(NH_3)_6^{3+}$ is either dried or outgassed, the proton of residual water is available for the ammine ligands and the complex is destroyed. The charge balance is restored by hydroxyl anions produced by water dissociation.

When the complex has been destroyed exchange with sodium does not remove the cobalt ion but NH_4^+

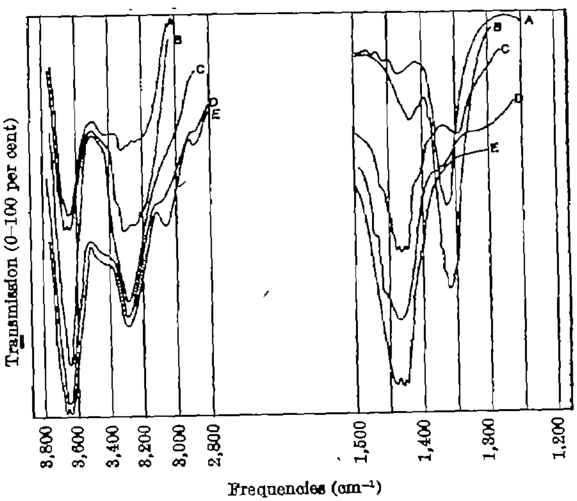

Fig. 1. *A*, dried at 20°; *B*, cooled and outgassed; *C*, outgassed at 20°; *D*, heated at 100°; *E*, NH_4-montmorillonite

is recovered in amounts equivalent to the cationic exchange capacity. Cobalt exists as probably cobalt hydroxide since it is in acid solution only (2 N) that it may be extracted. These facts are also supported by X-ray diffraction data: Co(NH$_3$)$_6^{3+}$ saturated montmorillonite expands as usual to 16 Å with glycerol while it does not expand when the complex has been destroyed.

Detection of Nanogram Quantities of Sulphur Hexafluoride by Electron Capture Methods

As sulphur hexafluoride is now used as a gaseous insulating and arc-quenching medium in electrical equipment, there is some interest in methods for its estimation in mixtures with other gases. The accompanying gas chromatogram (Fig. 1) demonstrates that electron capture methods can be applied to this end.

The detector used was as previously described[1,2] and was operated with a constant applied potential of 24 V with the carrier gas, nitrogen, flowing from a 4 mm × 70 cm chromatograph column packed with 80–100 mesh silica gel with subsequent dilution making the total gas flow-rate 500 c.c./min.

The peak illustrated was obtained with a 1-μl. load of 1/2,500 by vol. of SF$_6$ in air, that is, with approximately 2×10^{-9} g of SF$_6$, giving a maximum concentration of SF$_6$ in the detector of the order of 5×10^{-8} (molar). The ionization efficiency in the detector under these deliberately non-optimum conditions was approximately 2 per cent.

A proportion, 1/60 by vol., of CCl$_2$F$_2$ was included in the sample for comparison purposes. The ionization efficiency for the three peaks shown are in the sequence SF$_6$ > CCl$_2$F$_2$ > O$_2$, in accord with the known arc-quenching properties of these gases.

The detector efficiency decreases as the applied voltage is increased, but does so less rapidly for SF$_6$ than for most other gases, implying that the negative ion formed is relatively heavy. Thus the only peak occurring in the chromatogram when the applied voltage is 42 V is that due to SF$_6$. It is suggested, therefore, that it may prove possible to apply electron capture detectors to the routine estimation of the SF$_6$ content of mixtures of known gases, without preliminary chromatographic separation.

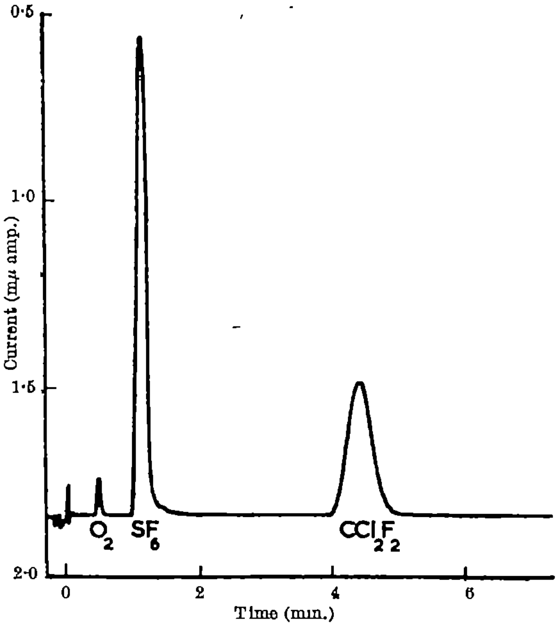

Fig. 1

I thank Mr. T. K. Morley and Imperial Chemical Industries, Ltd., for making available the sample of SF$_6$.

CRYSTALLOGRAPHY

X-ray Line Broadening in the Alkali Halides

During the past few years many investigations have been made of the effects of cold work on the X-ray line profiles of polycrystalline metals. Analysis of the profile broadening has been used to determine particle size, stacking fault probability and strain relationships. Using these same analytical methods, work is now in progress here on the investigation of broadening produced by cold work on face-centred cubic compounds of the alkali halides. This communication covers three of the compounds which have been investigated, namely, sodium chloride, potassium bromide and sodium fluoride.

Initially, the method of cold work was that which had been used in the examination of metal—the filing of block specimens. However, since the broadening produced in the alkali halides is relatively small, and it was therefore desirable to produce the maximum effect, it was found that crushing the specimens in an agate ball mill produced the better results. Similarly, annealing conditions have been varied to achieve maximum resolution in each compound studied, optimum conditions being related to melting point on one hand and solubility in water at room temperature on the other. Thus the broadening of a potassium bromide specimen decreases rapidly at room temperature under normal atmospheric moisture conditions and maximum resolution was achieved under these conditions after seven days. Sodium fluoride and sodium chloride, on the other hand, showed very slight effects at room temperature, and heating to 500° C for 1 h in the case of sodium chloride and 47 h for sodium fluoride was used to produce the annealed specimen. Even under these conditions it was not possible to resolve the sodium chloride and sodium fluoride lines to the extent that was achieved with potassium bromide.

Rachinger's method was used to resolve the α_1 and α_2 doublet and the integral breadths were obtained graphically. Graphs showing the values of integrated breadths versus $N = (h^2 + k^2 + l^2)$ are shown in Figs. 1, 2 and 3. Also shown in the graphs is the integral breadth computed from the Scherrer formula assuming a particle size of 1,000 Å.

The correction for instrument broadening was carried out by subtracting the broadening of the annealed specimen from that of the worked specimen, assuming, in turn, Cauchy and Gaussian shapes for the line profiles. As a result of particle size changes during annealing, the correction of instrumental broadening introduced anomalous particle size effects which were eliminated before proceeding to the strain determinations. The annealed profiles of sodium fluoride and sodium chloride also appear to have some residual strain broadening so that the strain function which was determined later relates to the excess broadening produced by cold work and not to the total strain. It has been found by previous workers that the actual line profiles lie between the Cauchy and Gaussian approximations, so the final values of strain measurements were obtained by taking the average values from these two extremes.

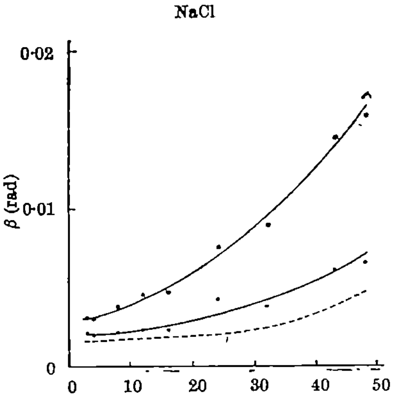

Fig. 1

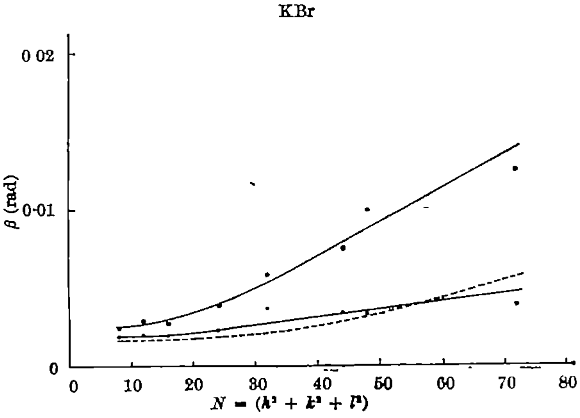

Fig. 2

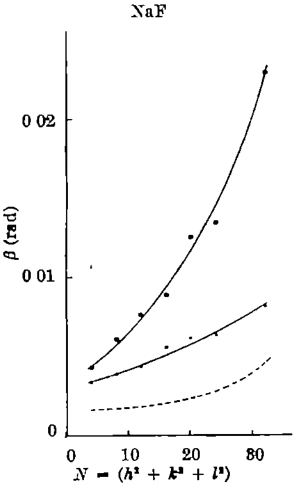

Fig. 3

Figs 1, 2 and 3. Graphs of measured integral breadth, β versus $N = (h^2 + k^2 + l^2)$, for sodium chloride, potassium bromide and sodium fluoride. Circles are for worked specimen and solid dots for annealed specimen. Broadening for particle size of 1,000 Å computed from $\beta = \frac{\lambda}{t \cos\theta}$ shown as broken line

The strain function $\xi \left(= \frac{\beta}{2} \cot\theta \right)$ was determined for the various orders of (100), (110), (111) reflexions and then averaged; this is compared with a mean value of the strain assuming isotropic strain distribution from the slope of the graph of

$$\beta^* \left(= \frac{\beta \cos\theta}{\lambda} \right) \text{ versus } d^* \left(= \frac{2 \sin\theta}{\lambda} \right)$$

where $\beta^* = \xi d^* + \frac{1}{t}$ and t is the average particle dimension, but in this case is not significant as explained here. The results of these strain determinations are shown in Table 1.

Table 1. STRAIN FUNCTION $\xi = \beta/2 \cot\theta$

Direction	[100]	[110]	[111]	Slope of $\beta^* - d^*$ graph
Sodium chloride	0·0022	0·0025	0·0025	0·0024
Potassium bromide	0·0024	0·0027	0·0030	0·0027
Sodium fluoride	0·0034	0·0037	0·0038	0·0037

Stress function = ξ × Young's modulus ($\times 10^{-8}$ dynes cm^{-2})

Direction	[100]	[110]	[111]
Sodium chloride	9·0–9·4	8·6	7·9–8·0
Potassium bromide	5·9–7·7	4·4–8·4	4·2–10·0

The particle-size dimensions could not be determined since the broadening due to particle size could not be separated from instrumental broadening, both of which influence the value of the intercept in the graph of β^* versus d^*.

In the case of sodium chloride an analysis of the profile shapes by a study of the Fourier coefficients of the broadening function, as outlined by Warren and Averbach, was carried out. The plots of A_n versus n confirm an appreciable strain broadening component in the worked specimen and a residual effect in the annealed specimen. Plots of the coefficients for multiple orders indicate a mean particle dimension of approximately 1000 Å, and absence of any peak shift precludes any apparent particle size effect resulting from stacking faults.

In order to obtain some idea of stress distribution in the crystals, the value of the strain function was multiplied by the respective values of Young's modulus for sodium chloride and potassium bromide. This could not be done in the case of sodium fluoride since the elastic constants for this compound were not available. It will be seen that the stress function for sodium chloride is reasonably constant for the three directions [100], [110] and [111]. In the case of potassium bromide the elastic constants quoted in the literature show a wide range of values; however, the spread of stress values obtained also suggests a constant stress in the three directions of about the same order of magnitude as for sodium chloride. Since three elastic constants are involved in the compilation of Young's modulus, the assumption of a constant value of stress in the three directions would enable one to compute the value of the elastic constants.

METALLURGY

Oxidation of Cupro-Nickel Alloys in Steam-Oxygen Mixtures

In the course of experiments in which a cupro-nickel alloy containing nickel 31·3 per cent, iron 0·50 per cent and manganese 0·73 per cent, balance substantially copper, was subjected to corrosion by steam–oxygen mixtures relatively rapid oxidation has been observed leading to the formation of a thick scale of corrosion product within a period of a few days. The experiments were conducted in an autoclave containing water, steam and oxygen at a total pressure of approximately 900 lb./in.^{2} and a temperature of 250° C, the saturation vapour pressure of steam at this temperature being 577 lb./in.^{2}. The results obtained plotted as a weight gain-time curve are given in Fig. 1. The corrosion product had a laminated multi-layer structure containing alternate nickel-rich and copper-rich phases; within the latter aggregates of substantially pure metallic copper were a prominent feature.

Segregations of nickel-rich and copper-rich phases and the formation of metallic copper have previously been reported in the scale present on copper–nickel alloys after dry oxidation in the temperature-range 700–900° C[1,2]. At these higher temperatures the formation of the discrete oxide phases NiO, Cu_2O and CuO can be accounted for on the basis of ionic and electronic diffusion, and the diffusion-controlled displacement reaction $Ni + Cu_2O \rightarrow NiO + 2\ Cu$ has been postulated to explain the formation of metallic copper[3]. However, at the relatively low temperature of 250° C used in our experiments, it seems improbable at first sight that a mechanism dependent on cationic diffusion as the rate-determining process is consistent with the rapid oxidation observed (Fig. 1).

An optical micrograph of a typical field illustrating in section the striated nature of the corrosion product formed on a specimen after 30 days is presented in Fig. 2 together with associated compositional variations revealed by the electron probe X-ray micro-analyser along the line marked X–X. During scans of 9-min duration, the intensities of characteristic X-rays excited by 29-kV electrons were recorded on a chart, from which the concentrations of nickel and copper in the corrosion product layers were estimated, using the known concentrations of these elements in the unoxidized alloy as calibration standards. Errors arising from X-ray absorption of fluorescence in the specimen were thought to be less than those introduced by unevenness of the specimen surface and were therefore neglected. Additional slow scans with the micro-analyser revealed that the nickel-poor regions were also depleted in iron and manganese.

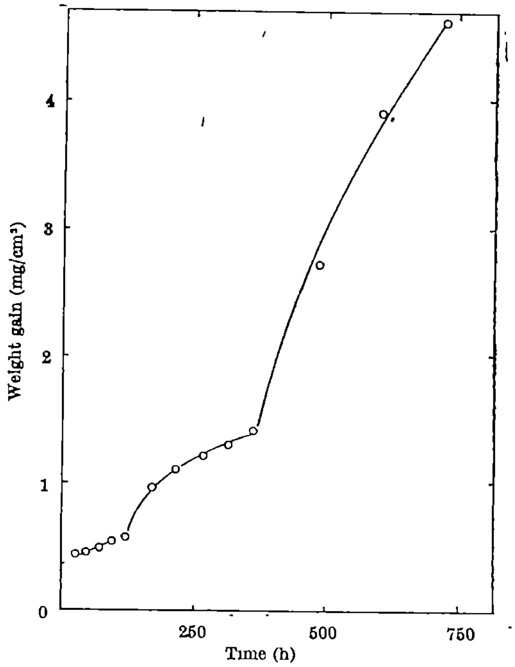

Fig. 1

The presence of metallic copper is immediately obvious when the scale is viewed under the optical microscope. The presence of the oxides NiO, Cu_2O and CuO was confirmed by X-ray diffraction analysis of a sample of corrosion product removed from the specimen surface.

On the basis of the foregoing evidence the main phases present in the respective layers labelled A–G in Fig. 2 have been identified as follows: A, unoxidized alloy + NiO; B, metallic copper + NiO; C, Cu_2O + NiO; D, predominantly NiO; E, predominantly metallic copper + a little Cu_2O; F, predominantly NiO; G, Cu_2O + a little metallic copper.

Some further metallographic evidence not reported herein confirms that the corrosion product layers are formed in the main as a consequence of inward diffusion of oxygen or some other oxygen-rich species. From Fig. 2 it is seen that at the boundary between corrosion product and uncorroded metal nickel is preferentially oxidized. It may be envisaged that the creation of vacancies in the solid solution lattice resulting from this process provides an enhanced opportunity for diffusion of the remaining cations, which will be predominantly copper, leading to the formation of agglomerates of substantially pure copper. Bands of metallic copper have been observed to appear at an early stage in the oxidation process when only a relatively small amount of corrosion product scale is present.

The degree of dispersion of the nickel-rich and copper-rich areas is presumably dependent on the respective rates of nucleation and growth of the

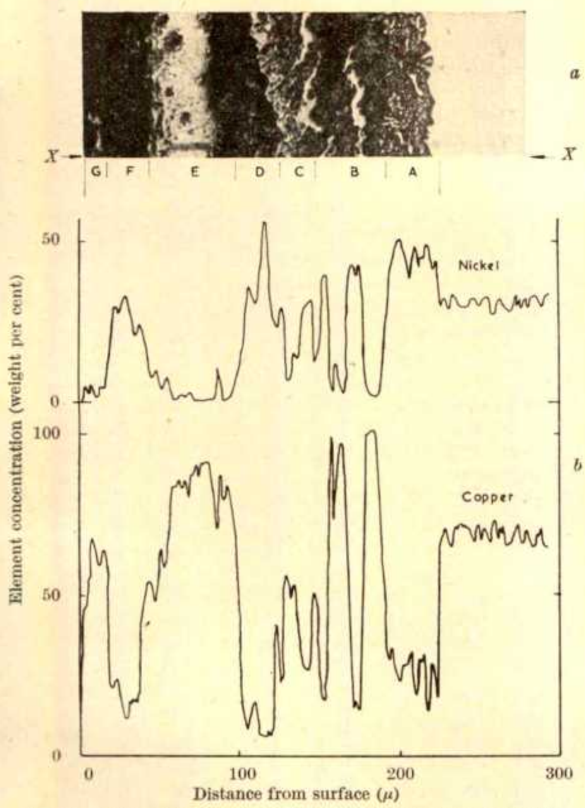

Fig. 2. *a*, Optical micrograph of a section through the corrosion layers; *b*, concentration curves of nickel and copper along the line *X–X*

phases, which will be influenced by the rate of inward diffusion of oxygen. Local variations in the latter dependent on space and time factors could give rise to the varying textures observed in different layers of the corrosion product scale.

CERAMICS

Corrosion of Corundum Crystals by Commercial Glasses

One of the most striking and least-understood aspects of refractory corrosion by molten glass is the relatively high rate of solution at the refractory-glass-gas interface, compared with that which occurs below the glass-level[1,2]. Any attempts to explain this phenomenon, or even measure it, are made exceedingly difficult by the complex nature of the materials involved[3,4]. This difficulty has been partially overcome by the use of single crystals of corundum as the refractory materials[5,6], thus eliminating factors such as porosity, pore size, pore shape, texture, etc.

Single crystals of corundum were immersed in four different commercial glasses (soda–lime–silica, barium crown, borosilicate and lead) for various times at temperatures ranging from 1,400°–1,500° C. Measurements were made both at the glass-level and below and rates of corrosion were calculated.

The measurements showed that not only did the rates of corrosion vary widely with different glasses, from 0·04 g cm^{-2} h^{-1} for barium at 1,500° C to 0·0005 g cm^{-2} h^{-1} for borosilicate at 1,400° C, but that there were also large differences between the rates of corrosion at the glass-level and below; for example, for soda–lime–silica glass, corrosion takes place approximately three times faster at the glass-level than below. It was also found that each glass impressed its own particular corrosion profile on the crystal (Fig. 1). The barium and the soda–lime glasses differed only in the acuteness of the indentation produced at the glass-level, but the lead glass caused a marked tapering effect on the crystal below the glass-level, as well as an indentation at the glass surface; the borosilicate showed practically no attack at the glass surface, but a gradual wear down the whole length of the crystal was observed. Photographs obtained of the cord formation showed that in some cases there was a tendency for the reaction product to fall, giving some protection to the lower part of the specimen (Fig. 2), and in others to rise to the surface, allowing fresh glass to reach the lower part of the specimen. This 'protection' effect however, did not appear to have any great influence on the glass-level phenomenon.

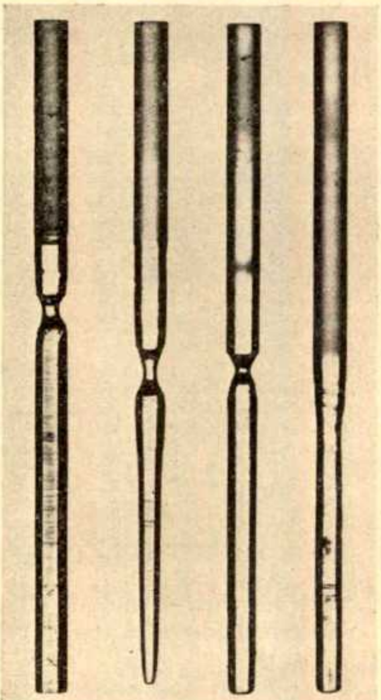

Fig. 1. Typical corrosion profiles obtained by immersing the corundum crystals in the four different glasses. The crystal on the extreme left has been immersed in soda–lime–silica glass for 5 h at 1,450° C and shows a sharp flux line indentation with practically no wear below this point; the specimen second from the left has been immersed in lead glass for 24 h at 1,500° C, it has a shallow and more elongated flux-line attack with considerable wear below the glass-level; the crystal second from the right has been immersed in barium crown glass at 1,500° C for $2\frac{1}{2}$ h and is similar to the specimen in soda–lime glass except for a sharper flux-line attack; the specimen on the extreme right has been immersed in borosilicate glass for 96 h at 1,400° C and shows practically no flux-line attack but a rather uneven wear down its whole length

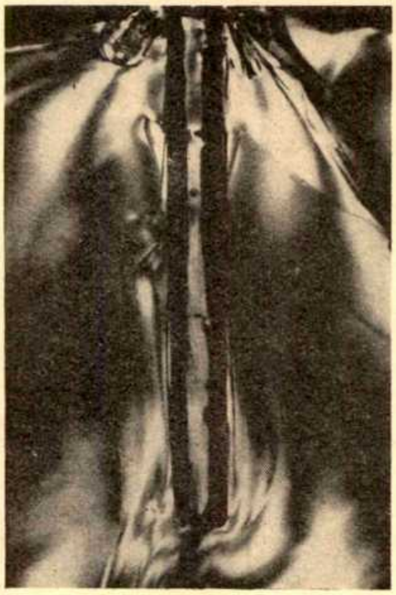

Fig. 2. A corundum crystal which has been frozen in borosilicate glass. The reaction product can be seen leaving the specimen and flowing downward; the photograph also shows some disturbance around the glass-level area

Even in cases where the reaction product rose to the surface, giving a relatively large amount of attack below the glass-level, specimens were still obtained which showed a marked indentation at the glass surface.

It was concluded that at least two corrosion mechanisms were involved; one at the glass-level, possibly closely associated with surface tension[7], and the other below the glass-level, where density currents and diffusion appeared to be the controlling factors.

BIOCHEMISTRY

Fate of Carbohydrates during Thermal Degradation of Tobacco

THE least-stable and least-explored group of substances in tobacco are the 'dynamic constituents', composed mainly of carbohydrates, organic acids, and unidentified substances of a related nature which are characterized by a high degree of mutability. Because of the high content and the reactivity of glucose and fructose in 'bright' tobacco, carbohydrates are considered the major constituent which undergoes modifications in harvested tobacco. Various oxidative and condensation reactions have been postulated[1-3], but the detailed nature of carbohydrate conversions and related chemical changes in tobacco have not been investigated.

The objective of this work was to examine the transformations of carbohydrates during the thermal degradation of flue-cured, 0–78*X* bright tobacco, crop 1961. The stemmed leaf was packed in glass cylinders at a density of 335 g/1,000 cm^3. The cylinders were closed hermetically, sealed with wax, and exposed to constant external heat in the range 24°–60° C for 1–9 days. The tobacco and the gaseous atmosphere were examined for compositional changes resulting from the breakdown of carbohydrates. The nature of the thermal conversions of glucose in the tobacco system and the relative distribution of its breakdown products were also determined on the same tobacco, which was sprayed with a glucose uniformly labelled with carbon-14 (Merck and Co., Ltd.).

The total content of the reducing sugars in tobacco was analysed colorimetrically by the modified method of Hawkins[4]. Water-soluble acids were determined by the method of Darkis *et al.*[5]. The dibasic acids were analysed on the F.N.M. model 500 gas chromatograph with a 2-ft. 'Carbowax' column[6] and by paper chromatography, using a diethyl ether/formic acid/water (5 : 2 : 1) system. The moisture content was determined in a Freas oven at 100° C for 3 h. The total carbon dioxide and oxygen content in the ambient was analysed on a C.E.C. mass spectrometer, type 21–103*C*, at an ionizing voltage of 70 V, ionizing current of 50 μamp. and a magnet current of 251·0 m.amp. The evolution of radioactive carbon dioxide was measured in a liquid scintillator L.S.C. : 10*B* after precipitation from sodium hydroxide solution as a barium salt. The total radioactivity present in the tobacco residue and in its water and ether extracts was determined by combustion and by counting in the ionizing chamber (Dynacon *M* 6,000-recorder model *R*–1,000).

Thermal degradation decreased the amount of reducing sugars and increased the free acids and water content in tobacco. The *p*H of tobacco decreased from about 5·5 to 5·3–4·9 per cent, depending on the extent of changes in composition. No detectable decrease in the weight of the thermally degraded tobacco samples could be observed as would be the case if the 'analytically disappearing' carbohydrates were fully oxidized to carbon dioxide and water. However, some of the changes were connected with the evolution of carbon dioxide and with an almost equimolecular consumption of oxygen from the atmosphere. Correlation between the molar conversion of sugars and its various reaction products indicated that several mechanisms of carbohydrate transformation took place during the thermal degradation of tobacco. Small amounts of the total carbon dioxide which was liberated may arise from the decarboxylation of acids.

The rate and the extent of the reaction were very sensitive to temperature. Up to 50° C, the quantitative compositional changes connected with the transformation of carbohydrates were linearly related to an increase in temperature. At higher temperatures, these changes were exponential.

The results were confirmed by examining the thermal conversion of radioactive glucose which had been introduced into tobacco. Depending on the temperature conditions used, approximately 0·64–6·04 per cent of the total carbon from dynamic constituents and/or 0·47–1·92 per cent of the total carbon from the radioactive glucose present in tobacco was oxidized to carbon dioxide. The material balance and the examination of the glucose conversion products indicated that a part of the 'analytically disappearing' carbohydrates lost its reducing power due to condensation with other naturally occurring constituents in the leaf. Depending on the temperature conditions, 5·8–46·0 per cent of the glucose was converted to high-molecular-weight complexes, remaining on the leaf during conventional sugar extraction. In addition, 7·7–29·5 per cent glucose was converted to a mixture of non-reducing, water-soluble, partial oxidation products and complexes. Approximately 1·7–3·6 per cent glucose was converted to the ether soluble compounds. Furfural and hydroxymethylfurfural were identified as some of the reaction products[7] by the ultra-violet and infrared analyses after elution from paper chromatograms at the R_F values of 0·78–0·84. Paper chromatograms of the ether extracts from tobacco, scanned on the Scanogram II (model R.S.C.–160), showed also the presence of wide area of radioactivity at the R_F range of 0·07–0·38. These glucose degradation products have not yet been identified. The gas chromatographic examination gave no evidence that dibasic acids were formed from glucose during thermal degradation of tobacco.

Autonomy of Protein Synthesis in Mutant Staphylococci with Impaired Respiration

ACCORDING to present concepts about the mechanism of protein synthesis, the ribosomes act as nonspecialized structures which synthesize the protein dictated by the transient attachment to the ribosome of a short-lived 'messenger RNA'[1]. It has been observed recently that the synthesis of messenger RNA in the bacterial cell is selectively inhibited by the actinomycins[2]. This specific mechanism of action of actinomycins gives a unique opportunity for analysis of the effects of blocking the synthesis of messenger RNA in the cell on the synthesis of proteins in the ribosomes. These effects can be comparatively investigated in normal staphylococci, as well as in mutant staphylococci with impaired respiration, which have been examined in some detail as a possible microbial model for cancer cells[3].

For an analysis of this problem we used the parent culture of staphylococci (*Staphylococcus aureus* 209), as well as mutants with impaired respiration induced by ultra-violet radiation, ultra-violet-2[4]. Parent staphylococci were grown in meat-peptone broth in Erlenmeyer's flasks containing 200 ml. of the nutritive medium, at 37°. Before the beginning of an experiment each flask was inoculated with 2 ml. of 24 h culture of staphylocci grown in the broth in shaking flasks and containing 6 × 10^9 of microbial cells per ml. Observations showed that in the prescribed conditions the logarithmic phase of growth of the culture begins 1 h after inoculation and continues for at least 3 h. Pure crystalline actinomycin *C* was used as an inhibitor of 'messenger RNA'. The inhibitor was added 1 h after inoculation, at the beginning of the logarithmic phase of growth of the culture. For an evaluation of the action of the inhibitor on the synthesis of proteins and of nucleic acids in the cells of staphylococci, two samples of 27 ml. each were taken from each flask: the first sample was taken immediately after addition of the inhibitor, and the second sample 3 h later. Of each sample 2 ml. were used for assays of protein content, and 25 ml. for assays of nucleic acids.

In the work with the slower growing mutants we used nutritive broth containing peptone (0·5 per cent), glucose (1 per cent), sodium chloride (0·5 per cent), and Hottinguer digest (0·5 per cent). Inoculations were made with 2 ml. of 48-h culture of mutants grown in shaking flasks and containing 6 × 10^9 of microbial cells per ml. In the parent culture of staphylococci growing logarithmically three-fold increase of the density of the culture is attained approximately in 3 h, but the same increase of density in the culture of mutants is reached only after 17 h. Therefore, in the work with mutants, the first sample for assays was taken immediately after addition of the inhibitor, and the second sample 17 h later.

Bacterial cells contained in each sample were separated from the nutritive medium by centrifugation, washed with distilled water, and used for assays. The protein content was measured by Folin's method[5]. Ribonucleic and deoxyribonucleic acids were extracted separately. RNA was extracted from microbial cells by 10 per cent perchloric acid at −4° for 17 h and assayed by the orcinol reaction. After removal of RNA from cells the latter were extracted with 10 per cent perchloric acid in the water bath at 90° for 15 min. and DNA contents of the extracts assayed by the diphenylamine reaction. Measurements are expressed in units of optical density. They were always made in duplicate, and frequently repeated.

Table 1 shows the results of our experiments. In the work with the parent culture of staphylococci the concentration of actinomycin used by us was 0·3 μg/ml., and in the work with mutants 0·006 μg/ml., since the latter were 50 times more sensitive to the action of actinomycin[6]. It is clear that actinomycin *C* in the concentration of 0·3 μg/ml. completely blocks (96 per cent of inhibition) synthesis of RNA in the cells of parent staphylococci. Under these conditions protein synthesis in the same cells is decreased by 60 per cent. An entirely different picture is observed in mutant staphylococci with impaired respiration. Actinomycin *C* in the concentration of 0·006 μg/ml. completely (by 99 per cent) inhibits synthesis of RNA in the cells of mutants, but this block produces no

Table 1. EFFECT OF ACTINOMYCIN *C* ON THE SYNTHESIS OF PROTEIN AND NUCLEIC ACIDS IN THE PARENT STAPHYLOCOCCI AND IN THE MUTANTS WITH IMPAIRED RESPIRATION ULTRA-VIOLET-2

Culture	Time incubated (h)	Actinomycin (μg/ml.)	Turbidity	Protein	RNA	DNA
1. Parent	0	0	0·168	0·058	0·272	0·081
2. The same	3	0	0·548	0·209	0·781	0·152
3. The same	3	0·3	0·336	0·138	0·291	0·122

4. Mutants ultra-violet-2	0	0	0·117	0·052	0·268	0·067
5. The same	17	0	0·439	0·183	0·496	0·113
6. The same	17	0·006	0·417	0·190	0·270	0·110
Percentage of inhibition			7	0	99	6

effect on protein synthesis, which continues at the same rate as in the control culture to which no actinomycin has been added.

The significance of these observations is self-evident. In the cells of parent staphylococci protein synthesis is controlled by 'messenger RNA', and as soon as the synthesis of messenger is blocked by the actinomycin the rate of protein synthesis decreases immediately. In the cells of mutant staphylococci this control mechanism is evidently lost, and protein synthesis goes on for some time autonomically, in spite of complete suppression of the synthesis of 'messenger RNA'. In other words, protein synthesis in the cells of mutant staphylococci is not controlled to the same degree as in the cells of parent staphylococci.

The validity of this conclusion is supported by some additional evidence. In accordance with some recent observations on the mechanism of streptomycin action in bacteria, streptomycin impedes the attachment of messenger RNA's to bacterial ribosomes, and in this way blocks the synthesis of proteins in the cell[7,8]. Since, in the mutant staphylococci examined by us, protein synthesis in the ribosomes is more autonomic and does not depend on the messenger RNA to the same degree as protein synthesis in the ribosomes of parent cells, one could theoretically expect that these mutants should be less vulnerable to the action of streptomycin than the parent cells. In fact, Gause and Kochetkova[9] in 1959 observed that mutant staphylococci with impaired respiration, ultra-violet-2 and ultra-violet-3, are five-times less vulnerable to the bacteriostatic action of streptomycin than the parent cells. At that time this observation was unexplained, but now one can see that it well agrees with our observation on the autonomy of protein synthesis in the cells of mutant staphylococci with impaired respiration.

Substrate Specificity of Maltose Phosphorylase

MALTOSE phosphorylase from *Neisseria meningiditis*, discovered by Fitting, Doudoroff[1], and Scherp[2], catalyses the following reaction:

$$\beta\text{-D-glucose 1-phosphate} + \text{glucose} \rightleftharpoons \text{maltose} + \text{phosphate} \quad (1)$$

Studies of specificity[1,2] showed that of many sugars tested only D-xylose could replace glucose as the acceptor for glucose transferred from the phosphate donor. The product was 4-*O*-α-glucosylxylose[3]. The sugar phosphate could not be replaced by the α-anomer[1,2].

Maltose phosphorylase has since been found in beer *Lactobacilli*[4] and *N. perflava*[5] and enzyme from the latter source can use 2-deoxy-D-glucose, D-glucosamine and *N*-acetyl-D-glucosamine instead of the glucose acceptor, giving rise to analogues of maltose.

We are interested in maltose phosphorylase because it is one of the few enzymes capable of synthesizing the α-1,4-glucosidic linkage *ab initio*, and may perhaps be the source of the primer required by other enzymes that synthesize the same linkage, for example, starch phosphorylase. Furthermore, the capacity of the enzyme to synthesize analogues of maltose leads to new substrates for other carbohydrases.

This latter aspect of maltose phosphorylase action has been examined with maltose phosphorylase from *N. meningiditis*. A range of sugars, many not previously tested as acceptors, were incubated with β-D-glucose 1-phosphate and enzyme. The following sugars could replace D-glucose and their rates of reaction relative to glucose (100) are also given: 2-*O*-methyl- (90), 6-*O*-methyl-D-glucose (20), 2-deoxy- (60), 3-deoxy- (55), 6-deoxy-D-glucose (95), 6-deoxy-6-fluoro-D-glucose (80), D-xylose (50). The following sugars were inert: 3-*O*-methyl- and 2,3-di-*O*-methyl-D-glucose, 1,5-anhydro-D-sorbitol (1-deoxy-D-glucopyranose), D-galactose, nigerose, isomaltose, sophorose, laminaribiose and gentiobiose. Where the sugar reacted as an acceptor, as shown by release of inorganic phosphate (equation 1), the synthesis of a new disaccharide was confirmed by its isolation from a paper chromatogram followed by acid hydrolysis to yield glucose and the test sugar.

Only D-xylose was previously known to replace D-glucose with the *N. meningiditis* enzyme. Five of the six new acceptor substrates are seen to be more reactive than D-xylose and therefore presumably conform more closely to the specificity requirements of the enzyme. It is of interest that any modification of glucose at C-1, as in 1-deoxyglucose, the glucose disaccharides and also methyl α-glucoside[1], entirely eliminates acceptor activity.

Our main interest in these investigations of specificity lies in the question whether the sugar phosphate can also be replaced by a 'foreign' sugar phosphate. In this case a maltose modified in the non-reducing glucose moiety would be formed. Such a disaccharide can be expected to provide other maltose-splitting enzymes with a more searching test of specificity than when the modification is carried in the reducing glucose moiety. To this end the 1-phosphates of β-D-galactose, β-D-xylose, 2-*O*-methyl- and 3-*O*-methyl-β-D-glucose have been synthesized and tested with maltose phosphorylase and glucose.

β-D-Galactose 1-phosphate was inert as a sugar donor; neither is free D-galactose an acceptor[1]. The phosphates of xylose and 2-*O*-methylglucose also failed to react, although the free sugars can substitute for glucose as acceptors. 3-*O*-Methyl-β-D-glucose 1-phosphate, however, reacted with glucose at a rate equal to that of β-glucose 1-phosphate itself, yet free 3-*O*-methylglucose is not an acceptor. Clearly maltose phosphorylase has different specificity requirements as between donor and acceptor molecules.

The synthesis of a new disaccharide, presumably 4-*O*-[3-*O*-methyl-α-D-glucopyranosyl]-D-glucose, has been confirmed by its isolation and hydrolysis to glucose and 3-*O*-methylglucose. Furthermore, the enzyme was apparently able also to transfer 3-*O*-methylglucose from the β-1-phosphate to 2-*O*-methyl-

D-glucose, 2,- 3- and 6-deoxy-D-glucoses, 6-fluoro-6-deoxy-D-glucose, and D-xylose, as shown by release of inorganic phosphate.

To our knowledge, this is the first time that any phosphorylase has been found to react with a 'foreign' sugar phosphate. This finding prompts the further pursuance of such investigations with this and other phosphorylases, with the prospect of the synthesis of modified sugar polymers having interesting chemical and biological properties.

We thank Dr. H. Scherp for the gift of *N. meningiditis*, Miss Anastasia Theofanides for culturing the organism, and the Department of Scientific and Industrial Research for a Special Research Grant.

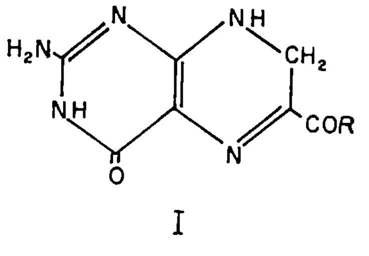
Synthesis of the Yellow Pteridine, Isosepiapterin

ISOSEPIAPTERIN is the name given to a yellow pteridine which occurs in *Drosophila melanogaster*, accumulates in the *sepia* mutant, and has been isolated in relatively large amounts from the blue-green alga, *Anacystis nidulans*[1]. Its structure (I, R = CH_2CH_3) and that of a closely related compound, sepiapterin (I, R = $CHOH{\cdot}CH_3$), have been elucidated chiefly by the work of Nawa[2] and Forrest *et al.*[3].

Present concepts[4] of the mechanism of action of thiamine suggest the intermediate formation in the decarboxylation of pyruvic acid of a relatively stable carbanion which can react non-enzymatically, for example, with acetaldehyde to give acetoin. Since a reduced form of 2-amino-4-hydroxypteridine (probably the 7,8- or 5,8-dihydro derivative) adds anionic reagents exclusively at the 6-position[5], it seemed feasible to use the catalytic action of thiamine to produce an anion from a keto-acid which, on reaction with the reduced pteridine, would give isosepiapterin or an analogue of it. Indeed, incubation of reduced 2-amino-4-hydroxypteridine, pyruvic acid, and thiamine at *p*H 9·0 yielded a small amount of a yellow compound (about 4 per cent of theoretical based on 2-amino-4-hydroxypteridine) which was purified as described here. This compound had an ultra-violet absorption spectrum identical with that of isosepiapterin and was oxidized by alkaline permanganate to 2-amino-4-hydroxy-6-carboxypteridine. Its structure is therefore believed to be I (R = CH_3).



I

Using α-ketobutyric acid instead of pyruvic acid, the following experiment was then carried out. 2-Amino-4-hydroxypteridine (Table 1) in 0·1 N sodium hydroxide (2·0 ml.) was hydrogenated in the presence of Adams' catalyst. After completion of the reduction (as evidenced by the complete disappearance of fluorescence), the reaction mixture was filtered and neutralized (2 N hydrochloric acid) as rapidly as possible. To this filtrate, *tris* buffer, α-ketobutyric acid, and thiamine were added (Table 1) and the whole was allowed to stand at 37° in the dark, when the solution gradually became yellow in colour. After 48 h, the solution was adjusted to *p*H 5 and applied to a column of 'Florisil'. After washing the column with water, the yellow band adsorbed at the top of the column was eluted with 20 per cent aqueous acetone and the eluate was concentrated. The yellow product was further purified by successive paper chromatography using the solvents 4 per cent sodium citrate and 1-propanol : 1 per cent aqueous ammonia (2 : 1). After elution from the final chromatogram and concentration *in vacuo*, the compound was obtained as yellow needles. It was found to be identical spectrophotometrically and chromatographically (Table 2) with natural isosepiapterin (I, R = CH_2CH_3) and was oxidized by alkaline permanganate to 2-amino-4-hydroxy-6-carboxypteridine. The yield in the first experiments was again low (3 per cent), but by varying the conditions (Table 2) a maximum yield of 22 per cent was obtained. This yield appears reasonable, since the overall reaction must involve a re-oxidation of the initial tetrahydro-2-amino-4-hydroxypteridine to a dihydro derivative (and presumably all three dihydro compounds—5,8; 7,8; and 5,6—may be obtained) followed by attack of the carbanion intermediate and then a further oxidation to the 7,8-dihydro compound.

Table 1

2-Amino-4-hydroxy-pteridine reduced (mg)	Isosepiapterin produced (mg)	Percentage of conversion of 2-amino-4-hydroxypteridine
5	0·2	3
1	0 14	10
0·5	0·12	17
0·2	0·06	22

Reaction mixture consisted of the reduced pteridine, 0 5 M; α-ketobutyric acid, 0 2 ml.; 0·5 M thiamine, 0·1 ml.; 0·1 M *tris* buffer, *p*H 9·0, 2·0 ml. The percentage conversion was calculated using the extinction coefficient of isosepiapterin at 440 mμ.

Table 2

Compound	Solvent		
	4 per cent sodium citrate	1-Butanol : acetic acid : water (4 : 1 : 1)	1-Propanol· 1 per cent ammonia (2 : 1)
6-Acetyl compound	0·27	0·34	0·41
6-Propionyl compound	0 27	0·49	0·53
Isosepiapterin	0·27	0·49	0·53
Sepiapterin	0·35	0 29	0·44

Synthesis of sepiapterin (I, R = $CHOH{\cdot}CH_3$) should be possible using this same procedure with α-keto-β-hydroxybutyric acid as the source of the side-chain. However, under conditions developed for maximal isosepiapterin synthesis, no sepiapterin was formed. When the OH group of this keto acid was protected by methylation (that is, using α-keto-β-methoxybutyric acid), a yellow compound was obtained in very low yield after reaction with reduced 2-amino-4-hydroxypteridine and thiamine, and this is presumably I (R = $CH(OCH_3){\cdot}CH_3$). However, we have not been able to hydrolyse this compound without destroying the yellow colour and fluorescence.

Although this synthesis of isosepiapterin is not unambiguous, it provides good confirmatory evidence for the structure of the compound and it might be developed for the synthesis of new compounds of the same type and/or derivatives of them. In addition, it opens up a possible new approach to the biosynthesis of isosepiapterin and sepiapterin and the related naturally occurring compounds such as biopterin (to which sepiapterin can be converted by chemical means). We are at present investigating the possible biochemical significance of this synthetic pathway.

Removal and Regeneration of the Cell Coating in Tumour Cells

Some ascitic tumour cells are coated with a mucopolysaccharide stainable by the Hale reaction[1]. Experiments were carried out to characterize more specifically the chemical nature of this cell coating and to study the dynamics of cell coat formation. Cells of ascitic mammary carcinoma *TA*3 were used *in vitro*. Experiments were carried out to determine whether some proteases and mucinases remove the cell coating, and, after removal, regeneration of the cell coating occurs.

Ascites cells were washed with and resuspended in Eagle's medium spiner, unless calcium was needed for enzyme activity, and then incubated at 37° C, with slow stirring, in the presence of one of the following enzymes or mixture of enzymes : pancreatin, crystalline trypsin, crude papain, crystalline papain, crystalline pepsin, testis hyaluronidase, and receptor-destroying enzyme (Behringwerke, Ag., Marburg-Lahn). The enzyme concentration was 1 or 2 mg/ml. of culture medium, except in the experiment with the receptor-destroying enzyme, in which case 4 drops of the buffer-enzyme solution per ml. were used. After 30–60 min of incubation* cells were washed in fresh Eagle's medium. Cells exposed to trypsin were incubated for 5 min at 37° C or overnight at 4° C. Treated cells were fixed in Love solution[2], and sections or smears were stained with Hale[3] or periodic acid–Schiff methods.

The cell coating, as stained with the Hale reagents, was removed partially or totally by pancreatin, trypsin, pepsin, and receptor-destroying enzyme. In contrast, crude papain, crystalline papain, and testis hyaluronidase were completely ineffective. Receptor-destroying enzyme had no action on the periodic acid–Schiff-positive component of the cell coat, and indeed this component may show even better after the enzymatic treatment. Trypsin, however, eliminated both the Hale and the periodic acid–Schiff positive material of the coat.

(Other experiments were performed to see if enzymes would remove the Hale-positive coating from fixed dead cells attached to a glass surface. Receptor-destroying enzyme was very effective in this respect after incubation of the cells with the enzyme for 5 h at 37° C. Pure neuramidase also very actively removed the cell coating. Pepsin and trypsin, in shorter incubation, were ineffective, and, in some instances, the coating stained more intensively with pepsin.)

To study the regeneration of the cell coating, washed *TA*3 cells were treated with receptor-destroying enzyme. After being uncoated by this procedure, they were cultured in Leighton tubes (Eagle's medium plus 10 per cent bovine fœtal serum). The cells were withdrawn 1, 2, 3, 4, 5, and 22 h after incubation (37° C), fixed in Love, and stained with Hale. It was observed, in these circumstances, that the cell coating reappeared in cells after a minimum of 1 h of incubation. However, the coats were less spinny than in the normal control cells.

The action of receptor-destroying enzyme and neuramidase on the cell coat indicates that sialic acid (neuraminic acid) is one of the components of the coating. This is in agreement with the indirect proofs provided by Weiss[4]. Since testis hyaluronidase is inactive, mucopolysaccharides attacked by this enzyme did not co-exist with sialic acid at the cell surface.

These experiments suggest that the Hale stain depends on the contiguity of the galactosamine–neuraminic acid bond at the cell surface. Neuramidase breaks this bond, causing a release of neuraminic acid, and then the Hale staining becomes negative. In contrast, the periodic acid–Schiff stain acts on galactosamine, as this stain is unaffected or even increased by previous neuramidase treatment.

The sialic acid must be bound also, directly or indirectly, to proteins because some proteases remove the Hale-positive coating from live cells *in vitro*. However, destruction of the coat does not occur when dead, fixed cells are exposed to proteases. Under these conditions, the Hale-positive coat may stain intensely, probably because masking proteins are removed[1].

The experiment on cell-coating regeneration shows that *TA*3 cells start to restore their coats of sialomucin within 1–2 h. It seems likely that cells acquire their sialomucin coat from products made in the Golgi zone[5]. The Golgi zone also has Hale-positive material, and this substance may be removed from sections by the receptor-destroying enzyme or sialidase.

Effects of Morphine on Uptake of Glucose and Synthesis of Glycogen in Muscle of Normal and Chronically Morphinized Rats

THERE is as yet no satisfactory explanation for the phenomenon of drug addiction. Morphine-induced biological dependence of a type which might be the basis of addiction in higher animals has not been demonstrated in unicellular organisms which have metabolisms independent of nervous or hormonal control, and no convincing explanation for such induced dependence arises from knowledge of the effects of morphine on the nervous system alone. There is little doubt that the chemical basis of addiction involves hormonal systems, and we further suspect that the site of addicting action may lie in mechanisms whereby hormonal effects are superimposed on the more primitive, intrinsic controlling mechanisms of cellular metabolism.

This view is encouraged by the results of experiments in which, preliminary to a more extensive study of the effects of morphine on the hormonal control of metabolism, we have compared the effects of morphine *in vitro* on the rates of glucose-uptake and glycogen synthesis in excised diaphragms of normal and of chronically morphinized rats.

Experimental procedures were based on those of Gemmill[1,2], Verzár and others[3,4]. Diaphragms from decapitated rats were trisected, the middle, vertebral portion used for the estimation of initial glycogen (we have confirmed the reliability of this procedure) and the two similar lateral portions were incubated in separate vessels for 2 h at 37° and *p*H 7·4 in aerated, phosphate-buffered saline (2 ml.) containing glucose (0·15 per cent), one containing morphine. Chronically morphinized rats were rats which had received daily injections of morphine (0·3 mg/100 g body-wt.) for 6 weeks. The control rats had received daily injections of saline for the same period. Glycogen was determined by the method of Good *et al.*[5] and glucose by Nelson's method[6].

The rate of uptake of glucose by diaphragms of normal rats was increased by the presence of morphine (1·9 × 10^{-4} – 1·6 × 10^{-3} M) in the buffered glucose–saline medium. In some experiments a fourfold increase was observed and in no case was the rate of glucose-uptake decreased by the addition of morphine. On the other hand, addition of morphine to diaphragms of chronically morphinized rats decreased the rate of glucose-uptake. The effects of morphine in a bicarbonate-buffered medium were similar to those in the phosphate-buffered medium. The results of experiments with 7·7 × 10^{-4} M final concentration of morphine are expressed in Table 1.

In the absence of added morphine there is no significant difference between the rates of glucose-uptake by diaphragms of normal and of chronically morphinized rats. This is confirmed by comparing chronically morphinized rats with control rats which had received saline injections (Table 2). On the other hand, the mean glycogen content of the diaphragms of the morphinized rats is somewhat higher than is that of the saline-injected controls ($P < 0{\cdot}1 > 0{\cdot}05$).

Table 1 EFFECTS OF MORPHINE (7·7 × 10^{-4} M) ON GLUCOSE-UPTAKE BY DIAPHRAGMS OF NORMAL AND CHRONICALLY MORPHINIZED RATS

	Glucose-uptake, mg/g wet tissue/h Mean ± *S.E.* (range) Control	+Morphine	Difference	*t*-test
Normal rats (21)	1·58 ± 0·141 (0·34–3·00)	2·58 ± 0·204 (1·45–4·00)	+1·0 ± 0·192	($P < 0{\cdot}001$)
Chronically morphinized rats (6)	2·46 ± 0·452 (0·98–4·08)	1·73 ± 0·355 (0·66–3·14)	−0·73 ± 0·269	($P < 0{\cdot}05$)

Table 2. INITIAL GLYCOGEN CONTENT AND RATE OF GLUCOSE-UPTAKE OF DIAPHRAGMS OF NORMAL AND CHRONICALLY MORPHINIZED RATS

	Glycogen, mg/g wet tissue Mean ± *S.E.* (range)	Glucose-uptake mg/g wet tissue/h Mean ± *S.E.* (range)
Control rats, saline-injected (12)	1·03 ± 0·145 (0·71–2·16)	1·83 ± 0·239 (0·96–3·54)
Chronically morphinized rats (16)	1·43 ± 0·157 (0·70–3·14)	1·87 ± 0·249 (0·38–4·08)

The rates of change of glycogen content during incubation of diaphragms of both normal and chronically morphinized rats are less affected by added morphine than are the rates of glucose-uptake. The mean rate of glycogen 'synthesis' in 9 normal rats was increased by addition of morphine (7·7 × 10^{-4} M) from 0·275 ± 0·132 to 0·347 ± 0·127 mg/g tissue/h, but we cannot claim that the difference, +0·072 ± 0·162, is significant. In 6 chronically morphinized rats the mean rate of glycogen synthesis was decreased by addition of morphine from 0·798 ± 0·206 to 0·398 ± 0·246, the mean difference being −0·40 ± 0·189 ($P < 0{\cdot}1 > 0{\cdot}05$). It would appear that the effects of morphine on glycogenesis or on glycogenolysis are secondary to direct effects on glucose-uptake. This view is further supported by our observations that morphine does not influence the rates of oxygen consumption and that it has relatively negligible effect on lactate production *in vitro* by diaphragms of both normal and chronically morphinized rats.

We thank the China Medical Board of New York, Inc., for grants for the purchase of apparatus.

Molecular Weights of Enzymes

IN a recent article Wright[1] put forward the hypothesis that the molecular weights of the enzymes tabulated by Dixon and Webb[2] fall near three series of numbers expressed by $2^n \times 12{,}000$, $2^n \times 16{,}000$ and $2^n \times 19{,}000$, n taking integral values 0–4. This hypothesis was based entirely on the experimental values themselves, mainly by means of graphical representation. A numerical test of the degree of fit of the data to the hypothesis was applied and indicated a good agreement; however, since this involved the arrangement of experimental values into groups, it contained the possibility of prejudice. It therefore seemed worth while to apply the more exacting method of the 'correlation function' used by Johnston, Longuet-Higgins and Ogston[3] to test the Svedberg hypothesis[4].

For this purpose, the null hypothesis is that values of log M are rectangularly distributed within the interval between the two successive predicted log values in which each falls. The predicted log values were those of Wright's hypothesis; the 59 experimental values used were taken from Dixon and Webb's table, omitting those for which a wide range is given. The estimated value of $F(N)$, the 'correlation function', was $+\ 0{\cdot}203$ with a standard error of 0·075. Since $F(N)$ is normally distributed, the significance of its deviation from zero is obtained from tabulation of the normal distribution, giving $0{\cdot}01 > P > 0{\cdot}001$; its positive value indicates grouping of the experimental around the predicted values.

Since this test does not involve a preliminary grouping of the experimental values it might appear to support the subjective judgments on which the hypothesis was based. However, since the relation of the experimental results to the predicted numbers is entirely defined by those numbers which were themselves based on a subjective judgment, the support is more apparent than real. All that it should be regarded as doing is expressing the agreement with hypothesis in a numerical form. Since the hypothesis itself contains four parameters (12,000, 16,000, 19,000 and 2) derived from the data, a good degree of fit is not surprising, and it is conceivable that other four-parameter hypotheses could be found giving equally good fit. Its author wisely councils caution.

I thank Prof. P. A. P. Moran for advice.

PHYSIOLOGY

Intimate Nature of Muscular Contraction

IT was originally proposed by Astbury[1] that muscular contraction was due to coiling or folding of the contractile proteins. A model of the structure of muscle sarcomere was recently proposed by A. F. Huxley and Neidergerke[2] and by H. E. Huxley and Hanson[3]; their model shows that filaments of actin and myosin slide past each other during contraction. A. F. Huxley[4] proposed a hypothesis of contraction in which it is assumed that active shortening or the development of tension is brought about by generation of relative translational forces between actin and myosin filaments at a series of points in the region of overlap.

In unstriated muscle there is evidence that contraction is due to coiling or folding of the contractile material. The effect of various substances on the contractile mechanism can be tested by using the usual glycerol-extracted muscle[5]. In a second method the muscle is allowed to die in solutions of various substances[6,7]. As the muscle dies its permeability and thus the excitability are destroyed, and the substances can come into direct contact with the contractile mechanism. Using both these methods it has been found that agencies, both physical and chemical, which denature proteins cause unloaded pieces of the transverse muscle of the frog, *Rana tigrina*, to lengthen without the application of any external force. Denaturation of proteins is caused by acids, bases, amides, detergents, guanidine and urea. Some of these substances cause relaxation of unloaded muscle when treated as here; these are acids, bases, urea, formamide and acetamide. It is therefore presumed that the contractile mechanism relaxes actively in these experiments.

Heat is a physical agent which denatures proteins. Its effect on unstriated muscle is most interesting. When unloaded circular strips of frog's stomach muscle are heated to 50° C for 10 min, some of them contract by 2–5 per cent and others lengthen by 10–30 per cent; further heating up to 60° C causes all of them to lengthen by 50–100 per cent. Muscles which have been heated to 50° C and are thus killed lengthen further if treated by the foregoing substances, which denature proteins. There is no doubt, therefore, that these substances act on the contractile mechanism. The action of heat and chemicals is thus complementary, and therefore they most likely exert an identical action on the contractile mechanism in causing relaxation.

The lengthening of unstriated muscle produced by denaturing agents may be due to proteins other than the contractile ones. That the contractile proteins take part in the lengthening is shown by the observation that if living unloaded frog's stomach muscle is immersed in urea, acetamide or formamide it becomes inexcitable but lengthens by more than 100 per cent in 1 hr; if the muscle is then transferred to saline it contracts and recovers its excitability[7]. The proteins in the living muscle had thus not yet been denatured in the usual sense, so that the lengthening could not have been due to the non-contractile proteins; the lengthening of the living muscle is presumably due to the close relationship between denaturation and relaxation. The effects of heat are similar[8]. If unloaded frog's stomach muscle is heated beyond 45° C, it becomes inexcitable but relaxes; if it is not heated beyond about 48° C, then it recovers. Relaxation continues if the muscle is heated to 60° C. The relaxation of living muscle passes imperceptibly into that of dead muscle. It is interesting to note that proteolytic enzymes, trypsin, papain and pepsin with hydrochloric acid cause lengthening of unloaded frog's stomach muscle whether living or killed by heating to 50° C (ref. 9); these enzymes are presumed to denature proteins before hydrolysing them. The lengthening of unstriated muscle by heat and other denaturing agents may be considered as the unfolding of peptide chains during denaturation. These experiments, therefore, elucidate the nature of both denaturation of proteins and relaxation of muscle.

Though unstriated muscle shows no special separation of two types of filaments as found in striated muscle, it is unlikely that there is any fundamental dissimilarity in contraction of the two kinds of muscle at the molecular level. Urea and other denaturing agents do not cause lengthening of isolated, unloaded, striated muscle as it is fully relaxed initially owing to the absence of tonus as found in unstriated muscle. But there appears to be some similarity in the contractile mechanisms of the two muscles as urea causes relaxation of loaded, glycerol-extracted, striated muscle fibres[10]. It is possible to apply the sliding filament theory to unstriated muscle. According to this theory the basic process in contraction of striated muscle is one of sliding; but some folding or crumpling of filaments at their ends may take place at higher degrees of shortening[11]. It may be assumed that in unstriated muscle the first stage is over, that is, the filaments have already slid, thus producing tonus of the isolated muscle and also accounting for the absence of cross-striations; its further shortening can only occur by folding of the contractile proteins.

Permeability Response of Cerebral and Cutaneous Blood Vessels to Vasoactive Agents

IN 1922, Forssman showed that solutions injected centripetally into the ligated right common carotid artery of the guinea pig were swept by the flowing blood first into the right subclavian artery and thence into the right vertebral artery[1]. His findings on the distribution of such injected materials have since been repeatedly confirmed, and the technique offers a ready means of subjecting the right half of the brain-stem and the right fore-limb in this species simultaneously to the action of possible vasoactive substances.

This route was later used by Broman in his investigation of the effects of various agents on the permeability of cerebral capillaries to trypan blue[2]. In this communication, we record some observations on the effect of certain materials on capillary permeability in the brain, among them some of the recently available pharmacological agents known to affect the permeability of capillaries in the skin of guinea pigs at a site of intradermal injection.

Guinea pigs were anæsthetized with 'Nembutal' and light ether, and the right common carotid artery exposed. One millilitre of a two per cent solution of Evans blue was injected into a saphenous vein. The carotid artery was then ligated, and the material under examination was injected in a volume of 0·3 ml. during a period of about 15 sec. When blueing of the fore-paw occurred, the colour generally developed after about five minutes. The animals were killed after 2 h, the brain was removed and fixed in formol-saline, and 24 h later it was examined for any blue coloration of the brain-stem on the right side. The materials injected and the results obtained are shown in Table 1. Broman made no mention of any colour-change in the right fore-paw, but as regards the staining of the brain-stem, our findings with histamine, sodium deoxycholate and Forssman antiserum agree with his.

It is apparent that in quantities verging on, and sometimes exceeding, the lethal dose, the small blood vessels of the skin and brain differ greatly in their permeability response for this dye to the materials used. Histamine, substance 48/80 and bradykinin all caused leakage of the dye into the tissues of the fore-paw, but no raised permeability was apparent in the vessels of the brain-stem. A blue coloration of the cerebral tissues was seen only after the injection of sodium deoxycholate and of a high-titre Forssman antiserum. These observations show that it is unsafe to extrapolate from experiments on the skin to the permeability effects of these substances on the small blood vessels of the brain.

Table 1

Substance	Quantity	Blue coloration	
		Fore-paw	Brain-stem
Histamine acid phosphate	0·3 mg/kg	+	—
Substance 48/80	5 mg/kg	+	—
Bradykinin	80–500 µg/kg	+	—
5-HT creatinine sulphate	500–2,000 µg/kg	—	—
Sodium deoxycholate	12·5–25 mg/kg	—	+
Forssman antiserum	12·5–50 µl./kg	—	+

We thank Dr. H. J. O. Collier for a gift of bradykinin.

Heparin and Blood Lipids in Fasted Individuals

IT is well known that intravenous administration of heparin induces in hyperlipæmic individuals a clearing of the plasma turbidity[1]. This effect has been explained by changes in physicochemical properties of the circulating lipids, consisting mainly of hydrolysis and dissolution of the fat in the plasma, due to the activation of a lipæmia-clearing mechanism[2]. There is also a suggestion that heparin could accelerate the removal of hydrolysed lipids from the blood stream since it was found that it induces a decrease in total fatty acids of plasma in hyperlipæmic rats[3].

The clearing effect of heparin has mainly been studied in hyperlipæmic individuals. There is a doubt whether heparin has any effect in non-hyperlipæmic states, since it has been suggested that it induces changes in serum lipoprotein spectrum only in hyperlipæmic subjects[4–7].

Therefore an investigation was undertaken to investigate the effect of heparin on plasma lipids and esterase activity in fasted subjects.

This effect was examined in 26 normal individuals after a 12 h fasting period. Blood was examined before the experiment and 5, 60 and 180 minutes after the intravenous administration of 2,000 units of heparin (Boots Pure Drug Co.).

An equal number of normal non-treated individuals were also examined in order to observe any possible spontaneous changes in blood lipids and esterase activity values during the experiment.

5 ml. of blood were drawn and mixed with 10 mg of potassium oxalate to prevent clotting and the plasma was separated by centrifugation.

The total lipids were measured by the sudan black method[8,9], the lipid phosphate by the Zilversmit and Davis method[10] and the plasma esterase activity by the method of Tuba and Hoare[11], using tributyrine as substrate.

The results are presented in Table 1. Total lipids and lipid phosphate are expressed in mg/100 ml. of plasma, and esterase activity as Tuba–Hoare units. The values are presented as mean values ± *S.E.* Normal non-treated individuals show practically no changes in total lipids or esterase activity of plasma

Table 1. Effect of Heparin on Lipids and Esterase Activity of Plasma

	Heparin			Control		
Time	Total lipids	Lipid phosphate	TBEsterase	Total lipids	Lipid phosphate	TBEsterase
Before injection (min)	324 ± 7·34	9·97 ± 0·26	351 ± 14·2	329 ± 7·24	10·28 ± 0·32	363 ± 15·0
5	257 ± 10·30	9·90 ± 0·29	419 ± 15·7	331 ± 6·40	10·26 ± 0·26	361 ± 14·2
60	279 ± 10·80	9·80 ± 0·27	384 ± 15·0	345 ± 7·72	10·14 ± 0·30	359 ± 14·3
180	317 ± 7·74	9·62 ± 0·25	356 ± 14·7	351 ± 7·18	10·19 ± 0·29	358 ± 15·1

during the experiment. Heparin-treated individuals show a significant decrease in total lipids ($P < 0·001$) accompanied by simultaneous increase in esterase activity ($P < 0·02$). These changes are observed 5 min after heparin administration. A return to the initial values was observed three hours after the beginning of the experiment. There was no change in plasma lipid phosphate in both groups. The decrease of plasma lipids and the increase of esterase activity observed indicate that heparin activates the plasma-clearing mechanism not only in states of hyperlipæmia but also in non-hyperlipæmic subjects.

Furthermore, the decrease of total plasma lipids could suggest that clearing is not only due to a change of the physicochemical properties of lipids but also to an accelerated removal of them from the blood stream. This conclusion is in agreement with the observations that heparin produces a distinct fall in the plasma lipids when given intravenously with different fat preparations[12–14] and in plasma total fatty acids when given in hyperlipæmic rats[9].

This research was aided partly by a grant from the Royal Hellenic Foundation for Research.

Effect of Bradykinin on Isolated Coronary Arteries

During an investigation of the comparative pharmacology of isolated vascular smooth muscle, it was noticed that the coronary arteries of the sheep were caused to contract by very small doses of bradykinin (Sandoz). Other substances were less active.

Spiral strips 2·5–4·0 cm long were cut from the left circumflex coronary artery of recently killed sheep or dogs, and were suspended in an isolated organ bath containing 10 ml. Tyrode solution, oxygenated with 5 per cent carbon dioxide in oxygen at 38° C. An isotonic frontal writing lever was used, counter-balanced to exert 2*g* tension. All preparations were left for 2 h before testing.

In 20 sheep coronary strips bradykinin caused a contraction within 15–30 sec. Repeated administration at 20-min intervals did not lead to a decrease in the response, which was usually constant, but sometimes increased in size over several hours. Fig. 1 shows a typical dose-response relationship. Many preparations were very sensitive to bradykinin, responding with a good contraction to as little as 0·001 μg/ml.; a few preparations required up to 0·1 μg/ml. Acetylcholine caused a contraction in doses of 0·025–5 μg/ml., and 5-hydroxytryptamine in doses of 0·3–1·0 μg/ml. Histamine caused contraction after administration of 100 μg/ml. The contraction caused by acetylcholine, but not that of bradykinin, was abolished by atropine. Adrenalin and noradrenalin caused relaxation in large doses (100 μg/ml.). In 2 of 8 isolated strips from dog's coronary arteries bradykinin and acetylcholine caused relaxation; they never elicited a contraction in the doses which were effective in sheep.

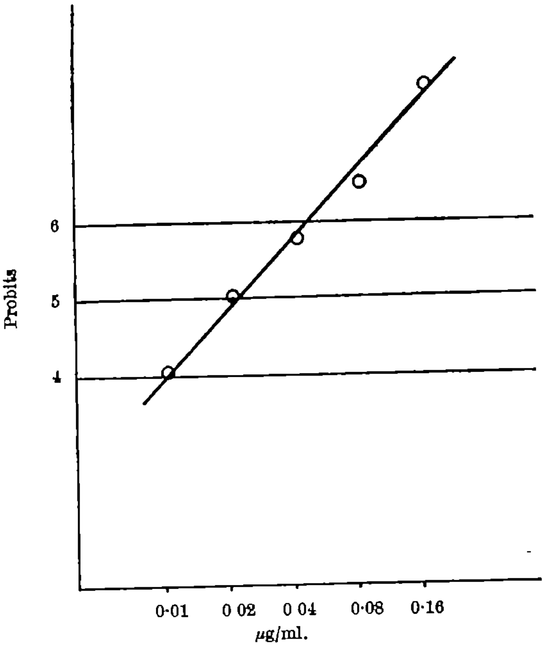

Fig. 1

It is interesting that this effect of bradykinin on the coronary vessels appears to vary with the species, and the great sensitivity of the sheep coronary vessels may make this preparation suitable for use in bio-assay.

I thank Sandoz Products, Ltd., for supplies of synthetic bradykinin.

Iron Content of Mammalian Breast Milk: Measurements in the Rat and in a Marsupial

LITTLE attention has been paid to the physiology of iron transfer through the mammary gland into milk, although a considerable amount of work has been done on absorption through the intestinal epithelium and on transfer from mother to foetus through the placenta. Direct measurements of the iron content of milk have mostly been confined to man and dairy animals. The average concentration of iron is approximately 0·5 μg/ml. in both human and bovine milk[1]. This value is lower than the levels of plasma iron in the respective species. In rat milk, on the other hand, a mean iron concentration of 7 μg/ml., a figure which is higher than plasma iron values, was reported by Cox and Mueller[2].

During the course of work by us and others in this Department, on various aspects of iron metabolism in lactating animals and in the developing young, we have accumulated a large series of measurements on milk iron in the laboratory rat and in the quokka, a macropod marsupial indigenous to Western Australia[3]. The results of these studies will be reported in detail elsewhere. It seems, however, appropriate at this stage to direct attention to certain similarities between the two animal species in respect of the iron content of milk.

Briefly, in both rat and quokka the iron content of milk assumes values considerably higher than the plasma iron and there is in both species a clear pattern of change in milk iron content with different stages of lactation. The iron in rat milk is highest at the beginning of lactation and then diminishes gradually (Fig. 1). It is of some interest to note that in the series represented in the graph the mean iron concentration taken over the whole period of lactation agrees well with the figure of 7 μg/ml. given by Cox and Mueller. In the quokka, where the young are confined to the marsupial pouch and to an exclusive milk diet for nearly six months of their extra-uterine life, milk iron remains consistently high throughout this period but a drop in the concentration occurs with the onset of weaning (Fig. 2).

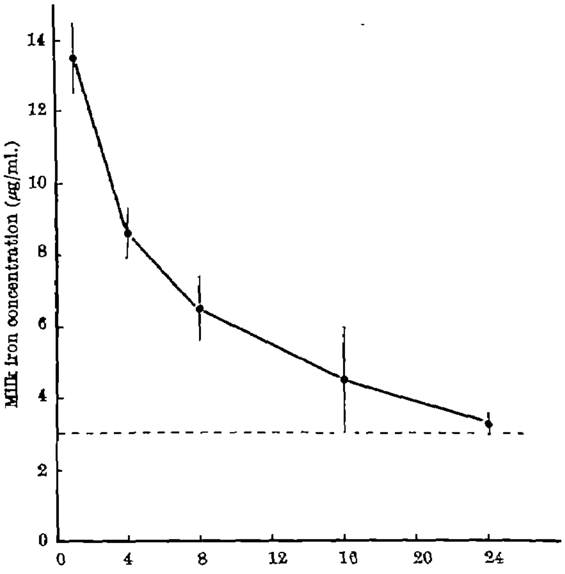

Fig. 1. Iron in rat milk. Each plot with a vertical bar represents the mean and its standard error for a group of 16 rats, except on day 1, where the group consisted of 9 rats. The horizontal broken line represents the mean plasma iron concentration in lactating rats

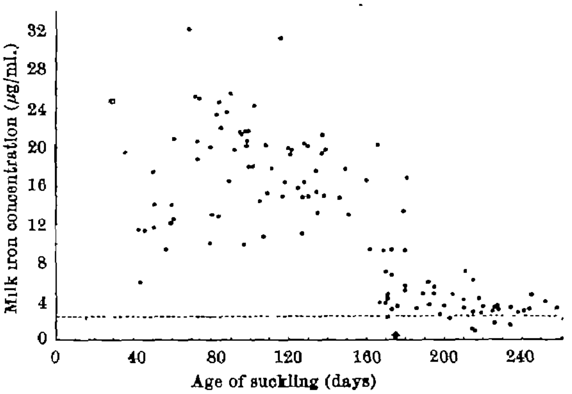

Fig. 2. Iron in quokka milk. Each plot represents a single measurement. The horizontal broken line represents the mean plasma iron concentration in lactating quokkas. The arrow on the abscissa indicates the average age at which weaning begins. The age of the young was estimated from measurements of physical characters as described by Shield and Woolley (ref. 7)

A physiological mechanism capable of concentrating iron into the milk is of obvious biological significance in those mammals the young of which are born relatively 'immature'. In the young quokka, the hæmoglobin concentration of blood rises from approximately 9 g/100 ml. at one month of age to 13 g/100 ml. at six months. The amount of non-hæmoglobin storage iron accumulated in the liver of six-month-old animals is greater than the corresponding fraction in maternal livers, though the weight of these young is only one-sixth to one-seventh that of the adult females (Kaldor, to be published).

In the case of the new-born rat, which grows faster and suckles for a much shorter period than the young quokka, it is more difficult to give a clear interpretation of the physiological significance of high maternal milk iron values. The suckling rat becomes anæmic before weaning[4] and this anæmia has been attributed to the inability of erythropoietic mechanisms to match the rate of body growth[5]. It has been shown that the iron content per unit body weight is also reduced at the time of onset of weaning[6], but in our own series young rats accumulated iron in proportion to their body weight throughout the suckling period (Ezekiel and Morgan, *J. Physiol.*, in the press). We are, as yet, unable to explain this difference in results.

Work is now in progress in this Department on the mechanism of iron transfer from plasma to milk. It is hoped that such studies may contribute to the general problem of iron transfer across cellular barriers.

HÆMATOLOGY

Johnson Type Haptoglobin

DURING our screening for haptoglobin patterns in different Jewish ethnic groups[1,2], we found a sample from a Kurdish boy (from Urmia in the Kurdish part of Persia) which appeared to contain a 'Johnson type of haptoglobin pattern'[3]. (We thank Prof. H. Harris (London) for comparing it with a known sample and identifying it.) Further examination of the family revealed the following results (Figs. 1 and 2). The mother of the propositus had a Johnson pattern of Hp and the father a Hp^{2-1} pattern; of the 7 children two had Johnson type Hp, one Hp^{1-1}, one Hp^{2-1}, two 'ahaptoglobinæmia' and one a hypohaptoglobinæmia. Two-and-a-half-fold concentration of the two ahaptoglobinæmic and the hypohaptoglobinæmic sera revealed the presence of haptoglobin in all of them. However, the exact pattern in them could not be determined.

In view of the presence of normal Hp^{1-1} in one of the children, it has to be assumed that the Johnson type haptoglobin is a combination of normal Hp^1 and Hp^J. The Hp^J is probably a mutation at the Hp^2 locus, or an additional allele. Lately Smithies has demonstrated biochemical evidence for a Hp^{2J} gene which is apparently a Hp^2 mutation[4]. Furthermore, he has demonstrated two Hp^1 polypeptides, a fast (Hp^{1F}) and a slow (Hp^{1S}). In the haptoglobin of the Johnson type Smithies demonstrated a Hp^{1S} and a Hp^{2J} polypeptide[4].

The hypohaptoglobinæmia which was found in three children is particularly interesting. The Hp^{2-1} pattern in the third generation from a father with a hypohaptoglobinæmia indicates that the hypohaptoglobinæmia is a combination of normal Hp^1 and Hp^{2J}. In family investigations Giblett and Steinberg found that a child of Hp^{2-1} (mod.) × Hp^{2-1} (mod.) mating was hypohaptoglobinæmic. Although they called it tentatively Hp^{2-2} they were not certain of the phenotype[5]. A phenotype Hp^2/Hp^{2M} looks just like Hp^{2-2}, but it can also be ahaptoglobinæmia. It was lately demonstrated that Hp^{2M}, is another Hp^2 mutation[4].

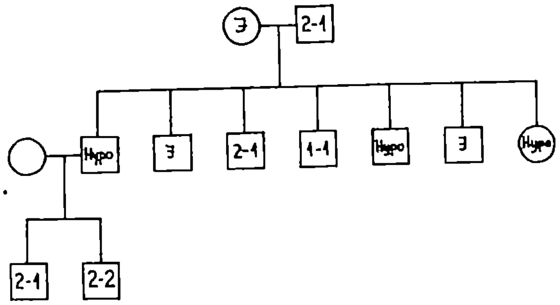

Fig. 1. The family tree

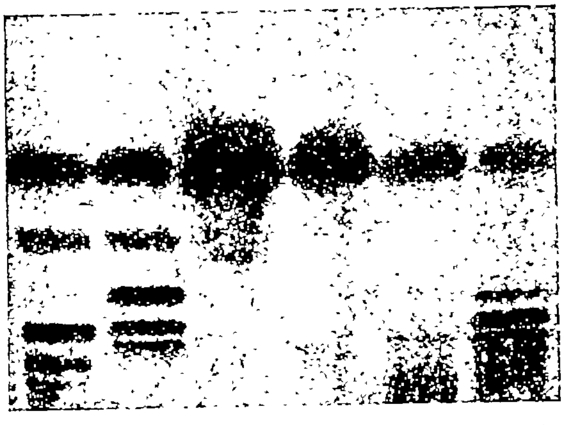

Fig. 2. Haptoglobin patterns (benzidine stain). Left to right: Hp^J, Hp^{2-1}, haptoglobinæmias (2·5-fold concentrated serum), Hp^{2-1}

It would appear, therefore, that the presence of Hp^2 in a genotype is associated with a decrease in haptoglobin production so that (in general) Hp^{1-1} > Hp^{2-1} > Hp^{2-2}.

The mutant forms of Hp^2 (that is, Hp^{2M} and Hp^{2J}), especially when associated with Hp^2, are even more likely to be associated with a decreased (or absent) haptoglobin. Only further family studies will prove if this hypothesis is correct.

Lately, Giblett found two more examples of the Johnson phenotype in samples from Hawaii. This makes a total of eight different families in the world known to contain the Hp^{2J} gene (or a slightly modified form) (Giblett, E., personal communication).

We thank Dr. E. Giblett for advice.

Waldenström's Macroglobulinæmia observed in Two Brothers

PRIMARY macroglobulinæmia (Waldenström's disease) has been observed in two brothers aged respectively 65 and 63 years. The clinical and hæmatological findings are summarized in Table 1. These two patients showed almost the same clinical picture: hæmorrhagic disorders with frequent epistaxis, hæmatoma, melœna; anæmia, increase of the lymphoid cells in the circulating blood, and in bone marrow. The eye grounds show a dysproteinæmic aspect and bilateral bleedings. Patient 1 (Louis D.) shows enlarged lymph nodes and splenomegaly.

Both patients have a high sedimentation-rate (140 mm/h), hyperproteinæmia (110 g/l.), and an *M* component (a narrow band in γ_1 zone) is observed in paper electrophoresis. This *M* component belongs to the biochemical type $\gamma_1 M$ ($\beta_2 M$) and does not penetrate into starch gel during electrophoresis.

The sedimentation patterns obtained in a Spinco analytical ultracentrifuge equipped with a Philpot–Svensson optical system shows three heavy components in both sera. These macroglobulins correspond to about 50 per cent of the whole serum proteins.

Table 2 shows the sedimentation-rate and the percentage of heavy components in the serum of the two brothers. Figs. 2 and 3 show the almost identical patterns obtained during ultracentrifugation of serum samples with increasing dilutions.

Table 1. CLINICAL AND HÆMATOLOGICAL FINDINGS

	Louis D.	Paul D.
	65 years old	63 years old
Hæmorrhagic disorders	Epistaxis once weekly, multiple hæmatoma, melœna	Epistaxis twice weekly, multiple hæmatoma
Blood	Anæmia R.B.C 2·5 m W.B.C. 9 000 Lymphoid cells 38–62 per cent	Anæmia R.B C. 2·8 m. W.B.C. 6·000 Lymphoid cells 23–54 per cent
Sternal puncture	Lymphoid elements 80 per cent Plasma cells 1 per cent	Lymphoid elements 50 per cent Plasma cells 10 per cent
Lymph glands	Enlarged Proliferation of cells of the lymphoid system overflowing the capsule	No palpable
Spleen	Enlarged	No palpable
Roentgen of the skull	No skeletal changes	No skeletal changes
Eye grounds	Enlargement of retina veins	Bilateral bleedings
Clotting tests	Normal	Normal
Sedimentation-rate	140 mm	140 mm
Total serum proteins	110 g/l.	110 g/l.

Table 2 ULTRACENTRIFUGATION COMPONENTS

	A		M_1		M_2		M_3	
	S_{20}	*p*. 100	S_{20}	*p*. 100	S_{20}	*p*. 100	S_{20}	*p* 100
Louis D.	4·5	51	19 2	43	29·5	6	35·7	
Paul D.	4·6	48	18·9	42	28·3	7	33·7	3

The mother of our two patients, 80 years old, showed no clinical manifestations and the ultracentrifugal analysis did not show any hyper macroglobulinæmia. However, we observed a minor narrow γ_1 band in paper electrophoresis and considerable increase of $\gamma_1 M$ globulin in immunoelectrophoresis.

It is interesting that the two brothers started Waldenström's disease at the same age (61 years), showing the same clinical manifestations and hæmatological disorders. Even more, the abnormal macroglobulinic components observed in the ultracentrifuge showed identical characteristics in both brothers, indicating a very similar or even identical physical structure.

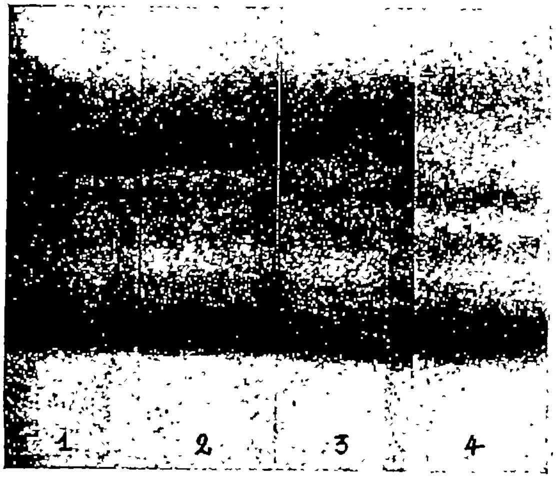

Fig. 1. Paper electrophoresis (veronal buffer *p*H, 8·6, staining with amidoblack 10 *B*)
Electrophoretical pattern of the serum in family D. 1, Louis D.; 2, Paul D., his brother; 3, Madame D., their mother; 4, Serum of normal human adult

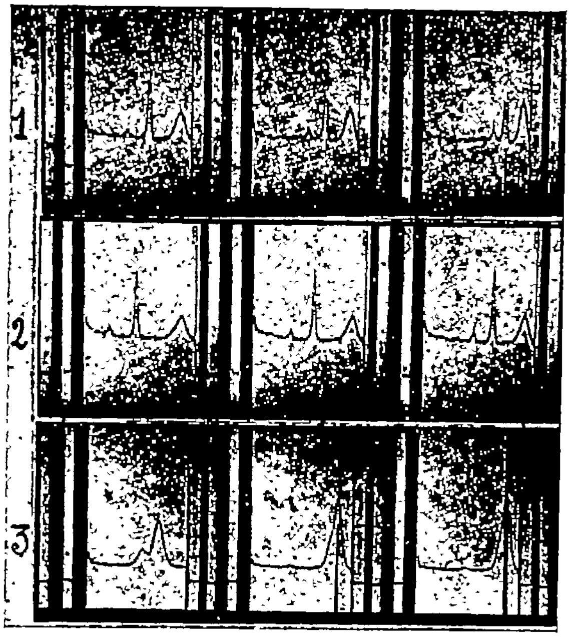

Fig. 2. Ultracentrifugation patterns of serum. 1, Louis D., 2, Paul D, 3, Madame D

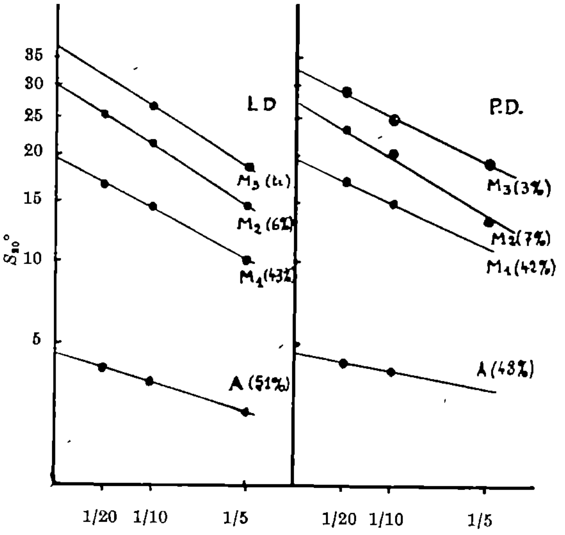

Fig. 3. Diagrams of the sedimentation-rate of the macroglobulinic components and their relationships with the dilution of serum

These findings, together with the observation of a minor *M* component of the $\gamma_1 M$ type in the serum of the mother, suggests the idea that Waldenstrom's disease might be an inherited syndrome due to some genetical disorder; the illness being only observed in the homozygotes of this abnormal gene. Unfortunately the familial studies are very often impossible as this disease is almost usually observed in people aged 50 years and more. So, one or both parents might be dead at that time and the observation of the grandparents is therefore absolutely impossible.

We hope that the publication of these exceptional findings will be followed by the study of the ascendants in other cases of 'primary macroglobulinæmia'.

Hæmogram of Normal and Starved Rats

THE bioassay of plasma erythropoietin by the starved rat method was introduced by Fried *et al.* in 1957[1] and has since been utilized by other investigators for evaluating erythropoietic stimuli. Gross changes in peripheral blood are apparent in all rats prepared for assay by withdrawal of food for varying periods of time.

The hæmograms of Sprague–Dawley rats before and after starvation for 80–96 h are shown in Table 1. The rats were kept singly in cages and had previously been fed on standard 'Purina' laboratory chow. Water *ad lib.* was provided during the starvation period. Pre-starvation body-weights were 155–170 g; after starvation, weights ranged from 100 to 121 g.

Mean levels of hæmoglobin, hæmatocrit and red blood cell count before starvation are comparable with other published values on 'normal' laboratory rats[2,3]. The hypochromia and microcytosis of the erythrocytes may be indicative of relative iron-deficiency, though iron (3 mg/10 g food) was included in the rat diet. High red blood cell, platelet and reticulocyte counts are a striking feature of the normal rat hæmogram. The intense reticulocytosis in the Sprague–Dawley rats before starvation is higher than that noted in an early investigation of normal albino rats by Orten and Smith[2]. Their figures reveal a mean of about 8 per cent reticulocytes in rats of comparable size.

The polycythæmia and hæmoconcentration seen after starvation (Table 1) are probably a reflexion of the degree of dehydration in the starved animals. Similar changes occur in rats given food but no water.

Inanition was accompanied by leukopænia which varied in individual rats from 1,600 to 4,300 white blood cells per cubic millimetre of blood. Differential leukocyte counts were not averaged because of marked variation from one animal to another. Granulocytes were generally less than 20 per cent of peripheral white cells in normal rats and no real differences were found in the starved animals.

Specific nutritional deficiencies known to influence hæmatopoiesis were not delineated in the starved rats. It seems possible, however, that part of the response of the starved rats to anæmic plasma, and indeed the slight erythropoietic effect of normal plasma or saline, may be the result of factors other than a specific hormonal erythropoietic factor. The suggestion has been made that polycythæmia plasma contains an inhibitor to erythropoiesis[4]. Any such inhibition is apparently easily overcome by anæmic plasma and even to some extent by normal plasma or saline. Reticulocytes in the starved rats increased from a mean of 0·8 per cent on the fourth day of starvation to 3·0 per cent 24 h after normal saline (3·0 ml.) alone was given intravenously.

Table 1. MEAN HÆMATOLOGICAL VALUES IN 88 SPRAGUE–DAWLEY RATS BEFORE AND AFTER STARVATION

	Before starvation	After starvation
Body-weight (g)	155–170	100–121
Hæmoglobin (g/100 ml.)	12·8	17·9
Hæmatocrit (%)	46	58
R.B.C (million/mm^3)	6 86	9·18
Reticulocytes (% of R.B.C.)	19	0·8
W.B.C. (per mm^3)	19,400	3,680
Platelets (direct count/mm^3)	934,000	669,000

PATHOLOGY

Pathological Proliferation of the Trophoblast Homograft in Women

ABOUT 1 g of trophoblast tissue, obtained in the course of legal interruptions in the second and third month of pregnancy, was grafted into the abdominal wall (mm. recti abd.) of: (*a*) 5 elderly women suffering from incurable cervical cancer; (*b*) 25 elderly women suffering from incurable cervical cancer and treated daily with 5 mg of œstrone acetate 3 weeks prior to grafting and consecutively until the removal of the graft; (*c*) 3 patients suffering from endogenous hyperœstrogenism.

5–7 weeks later the grafts were removed and examined histologically, about one half of the tissue being reserved for the estimation of chorionic gonadotropin (HCG).

The grafts from the cancer patients not treated with œstrogens were found, according to expectation, to have degenerated (Fig. 1), and no HCG could be detected by the Galli Mainini test. The grafts from œstrogen-treated patients showed no homograft reaction, were viable, and in addition marked proliferation with polymorphism of the nuclei and metachromasia were also present (Fig. 2). In some instances syncytial cells were found dispersed in the connective tissue (Fig. 3). Similar findings were obtained in cases suffering from endogenous hyperœstrogenism (Fig. 4).

The results demonstrate clearly that a high œstrogen-level suppresses the reaction of the host to homologous trophoblast tissue, and permits this not only to proliferate but also to synthesize HCG. It remains to be seen whether this action of œstrogen

is mediated by the hypophysis as some observations seem to indicate[1,2], or whether it is of a more direct nature; though, according to our experimental investigations, the œstrogen did not cause any synthesis of HCG *in vitro*.

Viability of Ehrlich Ascites Tumour Cells exposed to Sodium Chromate labelled with Chromium-51

Rajam *et al.*[1] were the first to report the binding of $Na_2{}^{51}CrO_4$ by Ehrlich mouse tumour cells, the viability of which was demonstrated by solid tumour formation after subcutaneous inoculation. Selecki[2], using a much greater isotope concentration (10 μc. per 10^7 cells), also reported subcutaneous growth. In view of the higher radiation exposure involved, it became necessary to confirm the viability of such preparations grown in the ascitic phase, in which gain in weight and subsequent transplantability can be compared directly with controls.

Ascitic fluid was pooled from 3 tumorous donor mice, counted in a hæmocytometer chamber, and divided into 3 portions. One was incubated with $Na_2{}^{51}CrO_4$ at a concentration of 10 μc. per 10^7 cells, washed with normal saline 5 times after Selecki's method[2], and adjusted finally to a concentration of 11×10^6 cells per ml. The second portion was incubated with normal saline alone, washed as before and adjusted to the same concentration. The third was stored for the same period, adjusted to the same cell concentration, but otherwise was undisturbed. Fourteen mice were inoculated with the first preparation, 7 with the second, and 6 with the third; the dose in each case was 0·3 ml.

Fig. 1 shows the similarity of gain in weight, due to ascites, in the three groups of mice; none of the differences is significant ($P > 0{\cdot}5$). To test the viability of treated cells further, serial replicate passage was originated from each of these mice and later from a similar preparation. Growth was vigorous through 9 and 8 transplant generations respectively before elective termination. Cytogenetic analysis of two mice in the first transplant generation

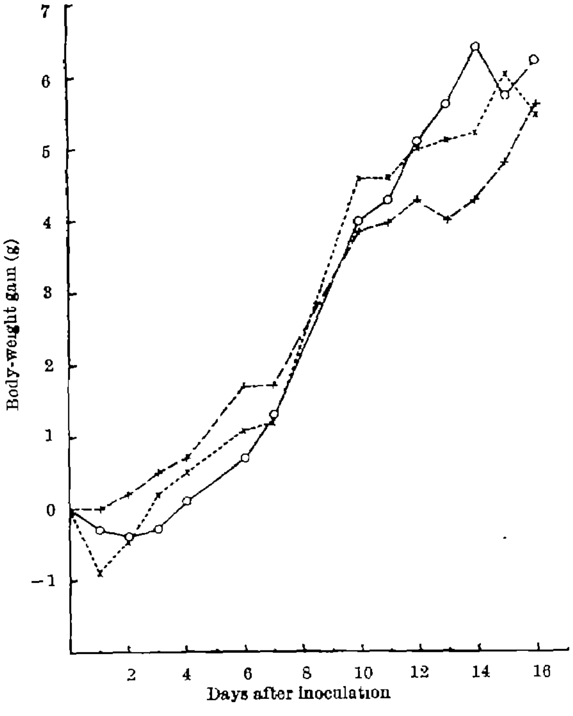

Fig. 1. Plot of weight gain due to tumour growth against days after inoculation. O, $Na_2{}^{51}CrO_4$ treated cells; + and ×, untreated control cells

showed no departure from the modal $2n = 43$ typical of the hyper-diploid tumour line maintained in this laboratory.

These findings confirm previous reports of the viability of Ehrlich ascites tumour cells incubated with $Na_2{}^{51}CrO_4$ even at high concentration. Grown in the more sensitive ascitic phase, a direct comparison of labelled and unlabelled cells in terms of weight gain, transplantability and—to a limited extent—chromosome complement has been possible.

I thank Dr. P. L. T. Ilbery, School of Public Health and Tropical Medicine, University of Sydney, for help with the chromosome analysis.

Experimental Production of Mesothelial Tumours of the Pleura by Implantation of Dusts in Laboratory Animals

IN view of the possible association between the development of mesotheliomas of the pleura and exposure to asbestos dust in people living in the Cape asbestos fields[1,2], a preliminary experiment was undertaken to see if it was possible to produce mesotheliomas, in animals, by injecting various forms of asbestos into the pleural cavities. 110 young rats, mice, and guinea pigs were used. The experiment has not yet been concluded as 45 of the guinea pigs, and four of the rats, are still alive thirty months after the start of the experiment. This is a preliminary report of our positive findings in 106 rats which have either died or have been killed.

The rats used were pure-bred Wistar rats, from the South African Institute for Medical Research stock; they were six weeks old at the time of inoculation. These animals were divided into eleven groups of ten animals; five groups were male, and six female.

The following dusts were used: (1) three samples of crocidolite dust prepared from virgin fibre obtained from mines in the southern and northern regions of the Cape asbestos fields and from a mine in the Pietersburg district of the Transvaal; (2) three samples of dust obtained from the mills of crocidolite mines in the same geographical distribution as those described in (1); (3) two samples of chrysotile dust prepared from virgin fibre—the first obtained from a mine in which the asbestiform serpentine occurred as an ore-body in basic rock, and the other dust from a deposit where the serpentine was found in dolomite; (4) a sample of amosite prepared from virgin fibre; (5) a sample of 99·9 per cent pure silica dust; (6) a sample of pure carbon black. (5) and (6) were used as controls.

The dusts were ground to a fine powder, and were suspended in normal saline at a concentration of 50 mg/ml. These materials were injected into the pleural cavities of the rats. The details of the preparation of the dusts and the method of inoculation will be described in a further publication. Dr. J. S. Harington analysed all these samples for the presence of oils and 3 : 4-benzpyrene[3]. These substances were found in all the crocidolite samples, very slight amounts in the amosite sample, but none in the chrysotile, silica or carbon black materials.

Bronchiectasis, a common feature among laboratory rats after the age of 6 months, was found in almost every animal. Indeed, this condition, with associated abscess formation or empyema, was the most usual cause of death. Seven animals with breast adenomata were all killed at a stage when these tumours had become so large that they were causing the animals marked discomfort. Eight animals developed reticulum-celled sarcomas and four mesotheliomas. These rats appeared to have died of these malignancies.

Two female rats died of large pelvic abscesses, and in one small group of animals no obvious cause of death could be found.

Pleural mesothelial tumours were observed in two animals inoculated with crocidolite fibres; one sample of the crocidolite being obtained from the Pietersburg area and the other from the northern portion of the Cape asbestos fields. Of the other two, one occurred in an animal inoculated with chrysotile fibre from the ore body, and one among the rats receiving the pure silica.

So far as can be ascertained from the literature[4], tumours of this type do not occur naturally in rats of the Wistar strain.

A further rat, a survivor of a dusting experiment in which animals were exposed to a fine chrysotile dust for 120 days, died 450 days after removal from the dust room. At necropsy, this animal was found to have a pleural mesothelioma. Macroscopically and histologically, the tumours in these animals were similar to those seen in human cases. In addition, hyaluronic acid secretion was demonstrated histochemically in four of these tumours, while in one animal, Dr. Harington was able to determine its presence chemically in the pleural fluid. The presence of hyaluronic acid has been an aid to the diagnosis of the tumours in human cases[5].

Fibro-adenomata of the breast have been frequently observed among female laboratory rats, and Ratcliffe[4] observed them to be the commonest tumour among stock Wistar rats. Reticulum-celled sarcomas were also not infrequently observed among these animals.

Table 1. OCCURRENCE OF TUMOURS IN RATS AFTER INTRA-PLEURAL INOCULATION OF 25 MG OF DUST

	Type of dust						
	Crocidolite fibre	Crocidolite ore	Chrysotile	Amosite	Silica	Carbon	Total
No of rats	30	30	20	10	10	10	110
Mesotheliomas	2		1		1		4
(Months after inoculation)	17 and 23		15		17		
Adenomas of the breast	2	4	1				7
(Months after inoculation)	11 and 18	19, 21, 23, 23	22				
Reticulum-cell sarcoma	3	3	1	1			8
(Months after inoculation)	16, 17, 17	16, 16, 22	16	22			
Sex of rats	20 F 10 M	30 F	10 F 10 M	M	M	M	
Survival time of group following inoculation (months)	11–25	7–30 (2 survivors)	11–30 (1 survivor)	14–30 (1 survivor)	11–24	12–22	

In view of these findings it was, therefore, accepted that the occurrence of these tumours was not the result of the experimental procedures.

It has been demonstrated that it is possible to produce tumours which appear to be arising from the mesothelial cells of the pleura by inoculating certain dusts into the pleural cavities of rats. One further tumour was obtained by exposing an animal to an asbestos dust cloud. The fact that these neoplasms were produced by silica and chrysotile asbestos as well as crocidolite fibre complicates the interpretation of these preliminary observations, and indicates the need for further investigations.

I thank members of the Unit who assisted in this experiment, those who provided the dust samples used, and especially Dr. H. Palmhert and Mary Hart, who helped in the animal inoculations.

An Early Test for Possible Skin Carcinogens in the Mouse: Effect of Different Doses of 3-Methylcholanthrene in Benzene Solution

AN early test for possible skin carcinogens in the mouse has been reported[1,2]. The test is based on a tetrazolium reduction method. It was demonstrated that the test could reveal the carcinogens in a blind test of 21 substances of which 7 were carcinogens.

The present communication gives the values obtained with different doses of 3-methylcholanthrene in benzene solution applied to a circumscribed area of the skin of hairless mice. The results are given in Table 1.

Table 1. TETRAZOLIUM TEST WITH DIFFERENT DOSES OF 3-METHYLCHOLANTHRENE

μg applied	% solution in benzene	No of mice	Test result
0·4	1/128	16	0·898
0·8	1/64	16	0·792
1·6	1/32	16	0·818
3·1	1/16	32	1·107
6·3	1/8	32	1·168
25·0	1/2	32	1·361
50·0	1/1	16	1·410

Terracini, Shubik and Della Porta[3] found a step-like increase in the tumour yield after single applications to mouse skin of different doses of DMBA. Studies are in progress at our Institute to find out if such a step exists for hairless mice exposed to single applications of 3-methylcholanthrene. The preliminary results ten months after the single painting are shown in Table 2.

Table 2. SKIN PAPILLOMATA OCCURRING TEN MONTHS AFTER A SINGLE SURFACE APPLICATION OF 3-METHYLCHOLANTHRENE IN BENZENE TO HAIRLESS MICE

% solution	No. of mice	Papillomata
1/64	30	1
1/32	30	1
1/16	30	20
1/8	30	22
1/1	30	34

These results demonstrate that such a well-known carcinogen as 3-methylcholanthrene gives negative results with the tetrazolium test when very small doses are given. The testing of unknown substances should therefore be performed with relatively strong, but non-ulcerative, doses. The possible specificity of the test, however, is given some further support by the preliminary results reported in Table 2. These seem to be in accordance with the conclusion of Terracini, Shubik and Della Porta[3]: "A critical dose level exists at which single application of carcinogens becomes fully effective".

Mineral Phase in Osteoporotic Bone

IN a survey of the incidence of fractures[1], particularly those of the head and neck of the femur, expressed in terms of population at risk, the distribution found made it quite clear that some must be of pathological origin. Such bones appear osteoporotic, and there has been a widespread assumption that the tissue component at fault is the calcium phosphate.

Should a change occur in the mineral, or in the calcium- and phosphate-level of its surroundings, one would expect to find changes in composition. Traditional methods of chemical analysis for calcium and phosphate cannot be profitably used, because the main need is to distinguish between a number of closely related calcium phosphates which might be present as mixtures. A further complication is that the mineral crystallites in bone have a very large surface area, so that adsorbed ions could produce misleading results. At present the most sensitive method for demonstrating individual components, which can be interpreted unambiguously, is X-ray diffraction.

A satisfactory method for distinguishing the various calcium phosphates involves taking photographs at room temperature, and then after heating to 1,000° C (ref. 2). At room temperature possible compounds are hydroxyapatite, octacalcium phosphate, monetite, brushite and calcium carbonate. After heating: apatite remains as apatite; apatite mixed with the other calcium phosphates, or apatite with phosphate adsorbed on to the crystal surfaces, reacts to form β-tricalcium phosphate, the proportion depending on the amount of excess phosphate present; calcium carbonate is transformed into calcium oxide.

One example where a difference is known in the tissue fluids surrounding the mineral in bone is in infants. These children have a higher serum phosphate than older children and adults. X-ray diffraction examination of bone from infants gave the hydroxyapatite pattern when unheated, and hydroxyapatite mixed with a little β-tricalcium phosphate after heating. Bones from the older age-groups gave hydroxyapatite only. In this case the different ionic concentrations in the surrounding fluids have been mirrored in the mineral composition.

To investigate possible differences in the mineral composition in osteoporotic bone the upper ends of the femur were used. At least three separate subjects were taken from each decade, and twice as many from the sixty-plus age-groups. All the bones taken from subjects aged below fifty-five looked normal. Above that age, approximately half looked normal, while half had sustained pathological fractures of the head or neck of femur. From each bone specimens were taken from cancellous bone in the head and neck, and compact bone from the top of the shaft.

On examination of the X-ray diffraction patterns it was found that bones from all age-groups, other than infants, gave hydroxyapatite lines only, both before and after heating, whether the specimens were normal or osteoporotic. This unchanged mineral composition suggests very strongly that the mineral crystallites have a purely passive role in any changes which may occur in osteoporosis. Further, the lack of adsorbed phosphate indicates that the calcium/phosphate ratio in the fluids immediately surrounding the mineral remains normal in osteoporotic bone.

Bilirubin Interference in the Diphenylamine Reaction

IN the course of analysis of human bile for the presence of mucosaccharide and deoxyribose-reacting material by the diphenylamine reaction[1,2], an unusual peak at 650 mμ was found. It was thought possible that this peak might be due to the yellow-green colour of bile, resulting from the presence of high concentrations of bilirubin and other pyrrolic breakdown products. This possibility was checked using pure bilirubin, deoxyribonucleic acid (DNA), and a mixture of bilirubin and DNA (Fig. 1). It can be seen that a solution of bilirubin (after heating at 90° C with 5 per cent trichloroacetic acid (TCA)) produces a peak at 650 mμ on boiling for 20 min with the diphenylamine reagent. DNA gives a peak at 600 mμ under the same conditions, whereas a mixture of bilirubin and DNA gives a peak at 620 mμ. The extinctions of DNA and bilirubin appear to be additive. Bilirubin also interferes in the Burton[3] procedure for deoxyribose, producing a strong green colour.

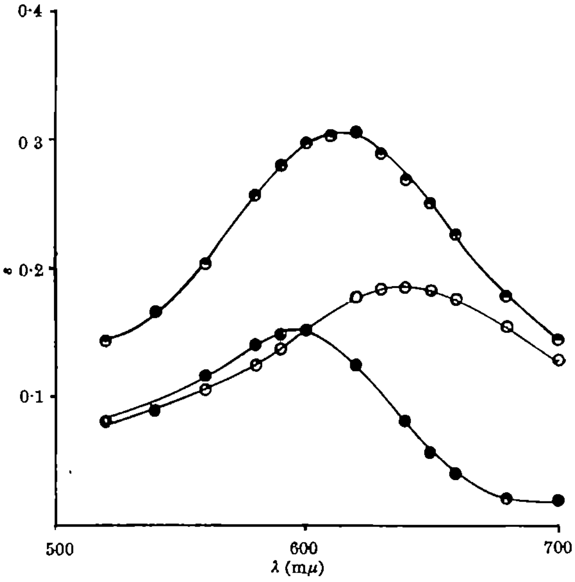

Fig. 1. Absorption spectra of the colours produced by heating bilirubin and DNA with the diphenylamine reagent. ●, 14 μg DNA in 2 ml. was heated in a boiling water bath with 4 ml. of diphenylamine reagent (ref. 1) for 15 min ; ○, 53 μg bilirubin dissolved in chloroform was mixed with 2 ml. 5 per cent trichloroacetic acid and warmed to evaporate the chloroform, 4 ml. of diphenylamine reagent was then added and the mixture heated on a boiling water bath for 15 min ; ◒, 14 μg of DNA and 53 μg bilirubin, treated as here, were heated for 15 min with 4 ml diphenylamine reagent

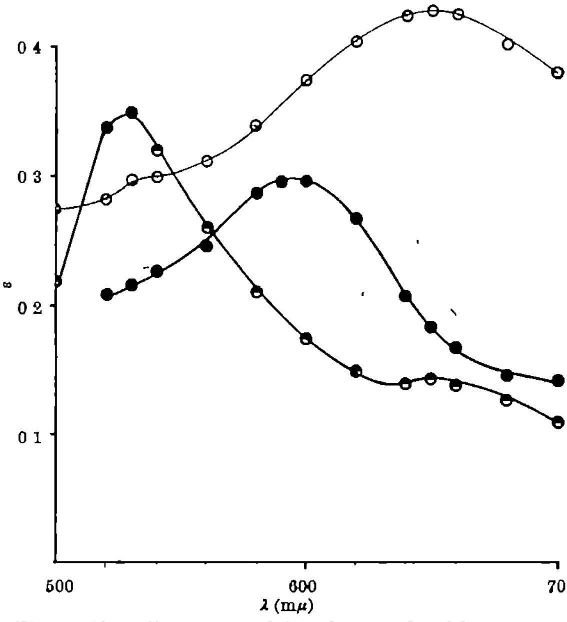

Fig. 2. Absorption spectra of the colours produced by heating. ○, Bile; ●, rat liver extract; ◒, jaundiced serum with diphenylamine reagent. 0·5 ml. of a 1 : 10 rat liver suspension, 0·5 ml. bile and 0·5 ml. of serum were each heated at 90° for 20 min with 4·5 ml. 5 per cent trichloroacetic acid; after cooling, the mixtures were centrifuged and 2 ml. of each supernatant was heated for 15 min in a boiling water bath with 4 ml. diphenylamine reagent. After cooling, the absorption spectra were measured using a Unicam *SP*-600

To determine whether this effect has any significance in physiological systems, we have studied the diphenylamine reaction in the serum of cases of obstructive and hæmolytic jaundice, in the drainage bile of a case of obstructive jaundice (cholangio-carcinoma of the hepatic duct), and in rat liver and rat serum 5 days after common bile duct obstruction. In such cases, after hot TCA extraction and centrifugation, the protein pellet is markedly blue in colour due to adsorption of a greater part of the bile pigment. The subsequent interference by bile pigment in the diphenylamine reaction probably depends on the relative proportions of bile pigment and protein and the affinity of the pigment for protein during the hot TCA extraction. With bile, for example, where the ratio of bilirubin to protein is high, the TCA extract itself is coloured by the bile pigment; however, in liver and serum where the protein content is much greater, the TCA extract is colourless even with high initial bilirubin-levels. Fig. 2 shows three representative curves for human drainage bile, human jaundiced serum and rat liver 5 days after common bile duct obstruction. It can be seen that bile shows intense interference in the diphenylamine procedure for deoxyribose reacting compounds, jaundiced serum much less, although a distinct shoulder is apparent at 650 mμ, and rat liver shows no obvious shoulder at 650 mμ. However, in rat liver, the decrease in extinction between 600 and 650 mμ is less than is found with TCA extracts of normal liver or with pure DNA (cf. Fig. 1).

It is apparent that in experimental work where a high bilirubin content is likely, that is, obstructive or hæmolytic jaundice, erythroblastosis fœtalis, etc., care must be exercised in quantitative interpretation of mucosaccharide and DNA-levels obtained by the diphenylamine reaction.

IMMUNOLOGY

An Agar-Gel Diffusion Technique for demonstrating Antibody Production by Lymph Node Cells in Tissue Culture

Many previous investigations on antibody production in tissue culture have utilized indirect systems for antibody detection[1,2]. Others have examined the incorporation of isotope-labelled amino-acids into antibody by tissue-cultured cells[3]. There are few reports concerning the production of precipitating antibodies to protein antigens by cells in tissue culture for more than 1–2 days, and these are often unconvincing. Preliminary experiments in our laboratory with fluid media from cultures of immune lymphoid tissue fragments were not successful in demonstrating precipitins. However, it was thought that the combination of the sensitivity of the agar-gel diffusion technique with the continuous antibody production of cells in tissue culture possessed possibilities of demonstrating precipitating antibody production. Accordingly, the following techniques were developed to reveal anti-bovine serum albumin antibody production by immunized lymph node cells in tissue culture.

New Zealand white rabbits ranging in weight from four to six pounds were immunized with bovine serum albumin by means of intravenous injections of 2 ml. alum-precipitated bovine serum albumin, 1 mg/ml., five days a week for one week, followed by three additional weeks of daily intravenous injections of 3 ml. bovine serum albumin. Precipitin titres were then carried out on the serum of these rabbits, and the animals with highest titres were given intradermal injections of 0·5 c.c. bovine serum albumin, 25 mg/ml. in Freund's adjuvant, into the foot-pads of both hind legs. 3–4 days later the popliteal lymph nodes draining the injected foot-pads were removed and fragments of the minced node were placed in tissue culture with Eagle–HeLa media and 20 per cent rabbit serum. Two types of tissue culture containers were utilized in these experiments, one a thistle tube with expanded superior portion and the other a narrow glass tube 5 mm in diameter and 6 cm in length. The bottoms of the narrow portions of both tubes were filled with 0·2 c.c. of 0·6 per cent agar mixed with 0·2 c.c. of bovine serum albumin in solution at a concentration of 1·0 mg/ml. Layered above the bovine serum albumin in agar was a 2 cm band of plain agar. Tissue culture media with lymph node fragment was placed on the superior surface of the layer of plain agar. The tissue cultures were incubated at 37° and, when necessary, additional tissue culture fluid was added to the media. Observation of the plain agar column for bands indicative of an antigen–antibody reaction was made, and when these bands occurred, cells were removed from the cultures for histological examination in representative experiments. At the same time, tissue culture fluid was removed and qualitative precipitin and ring tests were set up with appropriate dilutions of bovine serum albumin. These were uniformly negative. Controls consisted of normal non-immunized lymph node cells with the same tissue culture media, heated immunized cells in tissue culture, and normal and heated anti-bovine serum albumin serum.

Negative results were obtained with media alone, with media plus non-immune lymph node cells and with heated immunized cells. Immunized lymph node cells in the thistle tubes produced faint bands at 3–7 days, with gradual development of opacity and increasing band width during the next seven days. The two tubes on the right in Fig. 1 represent normal rabbit cells in tissue culture, and tissue culture media alone, both of which result in no bands or opacities in the agar. The second tube from the left demonstrates the multiple bands in plain agar which occur when anti-bovine serum albumin serum is placed in the thimble portion of the tube. Heated anti-bovine serum albumin serum gave bands similar to unheated serum. Immunized lymph node cells in tissue culture for fifteen days are present in the tube on the left, which demonstrates bands in the neutral agar layer. In addition to two distinct bands, there is a diffuse opacity present in the superior portion of the plain agar just below the tissue culture. It is probable that the bands occur so near the antibody-producing cells because of the large antigen excess present in the system. It is noteworthy that the bands occur in the central portion of the neutral agar when anti-bovine serum albumin serum is placed in the top of the tube.

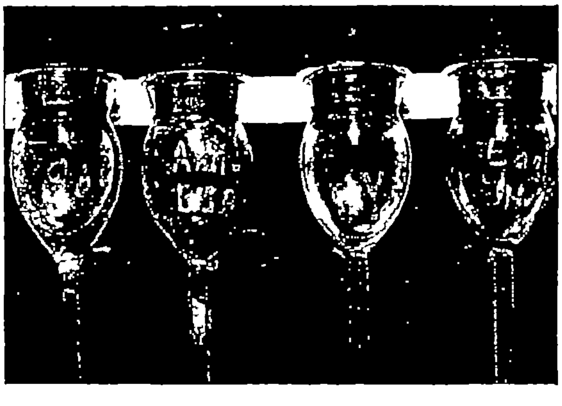

Fig. 1. Thistle tubes with plain agar in central portion and bovine serum albumin in agar at bottom of tubes. Note bands in agar below immune cells in tube on left, no bands in tube with normal cells second from right. Anti-bovine serum albumin serum gave multiple bands in central portion of agar column

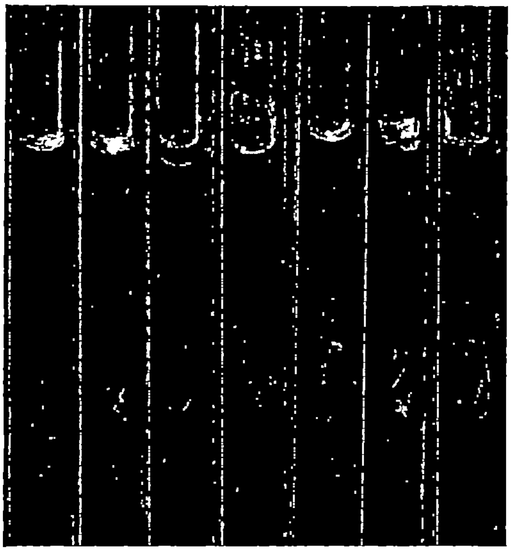

Fig. 2. Seven tubes with immune cells in tissue culture above neutral agar, with bovine serum albumin agar at bottom Multiple bands are present in all tubes except No 5 (from the left)

Fig. 2 shows the results of similar experiments performed with the smaller diameter glass tubes with no expanded superior portion. In these tubes the bands first became visible at 2–4 days, with gradual development of multiple bands in most of them by 10–12 days. The photograph was taken fourteen days after the lymph node fragments were placed in tissue culture. One tube in this group of experiments did not develop bands and it is assumed that the cells were not viable or had become undifferentiated into fibroblasts. Smears of representative tissue cultures associated with band production revealed mononuclear cells and cells resembling fibroblasts.

Some explanation must be given for the appearance of multiple bands in an agar-gel system utilizing bovine serum albumin and an anti-bovine serum albumin serum. It is possible that the variations in temperature which occurred when cultures were removed from the incubator and observed could account for this phenomenon, as has been previously described[4]. It is more probable that the multiple bands are a result of contaminants present in the commercial bovine serum albumin used in our experiments, thus resulting in the production of several antibodies by the host. It is possible that band formation is a result of preformed antibody release, rather than synthesis in tissue culture. The fact that heated anti-bovine serum albumin serum, but not heated immunized cells, gave bands in agar indicates that antibody synthesis by immunized cells in tissue culture has occurred.

The principal advantage of this method for studying antibody production *in vitro* is that it appears to offer greater sensitivity[5] in the detection of precipitating antibodies than the ring test or qualitative precipitin test applied to tissue culture fluid, since such fluids removed from tubes with band formation gave negative results when reacted with bovine serum albumin. Furthermore, the agar-gel tissue culture method is extremely simple to set up, easy to observe, and does not necessitate intermittent withdrawal of tissue culture fluid for antibody determinations. Finally, it has the advantage of giving some idea concerning the relative complexity of the antigen–antibody reactions occurring in the system.

Immunotolerance to Heterologous Heart in the Rat

WHILE seeking to demonstrate the organ specificity of cardiac tissue[1,2], an attempt was made to produce a specific antiserum in the rats using the phenomena of immunotolerance[3,4]. New-born rats received 18 daily intraperitoneal injections of homogenates of pooled organs (lung, liver, spleen, kidney and serum) of bovines, rabbits or guinea pigs during 3 weeks, followed by 3 weekly injections, a total of 220–250 mg protein being given to each rat. Other groups were given homogenate of heart or of heart and organ-pool and an untreated control group was included in each series.

At 7 weeks of age, the rats were test-bled and given weekly injections of 10 mg protein of heart homogenate of the same species as before. Blood was taken after 2, 3 and 4 injections : this communication refers to results obtained with serum from the 4th bleeding.

Sera were examined against the appropriate heart in the tanned red cell hæmagglutination test and by capillary precipitation and complement fixation tests using the methods previously described[1,2]. Table 1 shows that the pre-treatment with heart and/or organ-pool homogenates significantly decreased the production of antibodies to heterologous heart injections.

Table 1. TANNED RED CELL HÆMAGGLUTINATION TESTS IN IMMUNOTOLERANT RATS INJECTED WITH HEART HOMOGENATE

Tolerant to: (species)	Pre-treatment with organ-pool	pool+heart	heart	Controls	*S.D.* (*P*)
Rabbit	41/53*	13/19	15/31	38/38	< 0·001
Guinea pig	12/15	—	4/18	18/19	< 0·001
Bovine	22/32	24/28	26/29	26/28	0·05

*No. rats with titre > 1 40/total in group.

In the passive hæmagglutination test, immunotolerance was most marked in respect of organs of rabbit and guinea pig, the heart homogenate being more active than the organ pool. No differences could be demonstrated between the specificity of the antibodies produced by animals pre-treated with heart or with organ-pool. In the case of rats given injections of bovine tissues, the immunotolerance produced was much less marked, and organ-pool was more active than heart.

Similar trends were obtained in the precipitation and complement fixation tests although the proportion of controls producing antibodies was much smaller in the groups treated with rabbit and guinea pig organs (Table 2). There was no correlation between production of the different types of antibody by a specific animal nor did the production of a high titre in one test necessarily imply a positive reaction in another. Rats pre-treated and later challenged with bovine antigens showed dissociations between

Table 2. COMPLEMENT FIXATION (C.F.T.) AND PRECIPITIN TESTS (P.T.) IN IMMUNOTOLERANT RATS INJECTED WITH HEART HOMOGENATE

Tolerance to: (species)		Pre-treatment with: organ-pool	pool+heart	heart	Controls	*S.D.* (*P*)
Rabbit	C.F.T.	0/37*	—	0/31	13/30	<0·001
	P.T.	3/37	—	4/29	18/30	<0·001
Guinea pig	C.F.T.	4/15	—	0/18	10/20	<0·01
	P.T.	4/15	—	1/19	15/21	<0·001
Bovine	C.F.T.	3/30	0/29	0/29	26/28	⋞0·001
	P.T.	2/32	1/28	1/29	26/28	⋞0·001

*No. rats positive/total; C.F.T. ≯ 1·20; P.T. ≯ 1 mm. precipitate.

the results of the passive hæmagglutinations and the other tests; immunotolerance in the latter being established to a much more significant degree. Moreover, a number of pre-treated rats already showed circulating antibodies in sera taken before the course of immunizing injections. This dissociation between the results of different tests, interesting in itself, has been noted by other workers[5] and will be discussed elsewhere.

In the cases of rats injected with rabbit and guinea pig tissues, a similar degree of immunotolerance was found in respect of direct hæmagglutination of the appropriate erythrocytes. An unexplained finding was a drop in titre in the complement fixing and direct agglutinating antibodies of certain animals between, for example, bloods taken after the second and fourth injection, while the titres in the tanned red cell passive hæmagglutination test continued to rise.

We have previously postulated[1,2] the existence of organ-specific antigen in cardiac tissue and the present experiments provide further support for this view. In theory, one might expect the tolerance produced against individual organs of a foreign species to be obscured by the general immunotolerance to the species. In fact, it has been possible to produce immune tolerance, for example, to human erythrocytes in rabbits but not to blood-group antigens[6].

However, the present successful production of organ-specific immunotolerance may be associated with immunological properties peculiar to cardiac tissue and the giving of much larger amounts of antigen than usual[7,8] during the pre-treatment phase.

RADIOBIOLOGY

Modification of Radiation Effect on Mammalian Tumour Cells by Pharmacological Agents

IN an earlier communication it was demonstrated that the effect of X-irradiation on the reproductive capacity of mammalian tumour cells could be modified by the incorporation of relatively small amounts of halogenated pyrimidine deoxyribosides into the DNA of these cells[1]. Additional work has now been completed in which the time and dose relationships of administration of the drugs and variation in the ionization density of the radiation have been examined. The P–388 lymphocytic leukæmia of the $DBA/2$ mouse and its use by serial dilution assay to examine cell reproductive capacity have been reported in detail[2]; the TD_{50} is defined as the mean number of cells necessary to produce 50 per cent tumour 'takes' in a group of recipient animals of the same strain, and the 'surviving fraction' is the result of control TD_{50} divided by experimental TD_{50}.

Table 1. EFFECT OF X-RAYS ON TUMOUR CELLS TREATED WITH 5-IODODEOXYURIDINE

Treatment	Mean TD_{50} Tumour cells/mouse	Surviving fraction
Control	2 7 (2·3–3·0)	
IUdR, 100 mg/kg/day, 4 days	3·1	
IUdR, 100 mg/kg/day, 35 days	3·0	
1940 rads, 3-MeV X-rays	170	0·016
1940 rads, 3-MeV X-rays, IUdR, 100 mg/kg/day, 4 days	840	0 003
1940 rads, 3-MeV., X-rays, IUdR, 100 mg/kg/day, 35 days	1,320	0 002

In the earlier investigations, 5-iododeoxyuridine (IUdR) was administered daily to tumour-bearing donor animals by single intraperitoneal injection for 4 days prior to irradiation and/or assay to determine cell reproductive capacity. The mean doubling time of cells of this tumour is approximately 15 h[2], and it was felt that no significant additional incorporation of the halogenated DNA precursor would result from more prolonged contact with the drug. Table 1 shows the results of an experiment designed to test this supposition, in which tumour cells were exposed to 35 daily injections of IUdR at a dose of 100 mg/kg body-weight. The P-388 tumour is routinely transplanted on the 7th day following inoculation of 10^6 cells intraperitoneally, hence this investigation involved the daily exposure to the halogenated analogue through five transplant generations of the tumour. This course of administration of the drug did not raise the TD_{50} for unirradiated tumour cells, and the potentiation of radiation effect noted in these drug-treated cells was only slightly greater than that observed when the tumour cells were exposed to the halogenated analogue for only 4 days prior to irradiation, paralleling the *in vitro* observations of Kaplan *et al.*[3] that in excess of 4–6 cell doublings in the presence of the halogenated analogue no significant increase in drug incorporation can be made by further prolonged contact.

Szybalski has suggested that one mechanism by which the halogenated pyrimidine deoxyribosides act is to render the DNA of those cells which have incorporated them more fragile, hence subject to damage by ionizing events which alone would transmit insufficient energy to produce this damage[4]. It seemed worth while, therefore, to examine the effects of densely ionizing radiation (fission-spectrum fast neutrons) on cells the DNA of which contained halogenated analogues, as the dose-response to these radiations is 'single-hit' in type[5], that is, the passage of any one particle is sufficient to cause loss of reproductive capacity of the cell. In Fig. 1, the dose-response to fission-spectrum fast neutrons is shown for tumour cells exposed to IUdR, 300 mg/kg/day for 4 days prior to irradiation; no significant difference is observed between the response of these cells and that

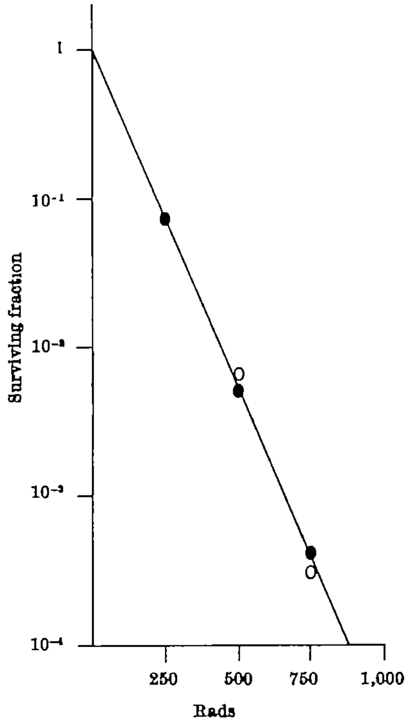

Fig. 1. Dose-response, fission-spectrum fast neutrons. ●, P-388 leukæmia, *in vivo*; ○, P-388 leukæmia, *in vivo*, previously treated with IUdR, 300 mg/kg/day × 4

of cells which had not been pre-treated with the halogenated analogue.

Finally, tumour-bearing donor animals were treated with the third of the halogenated pyrimidine deoxyribosides, 5-chlorodeoxyuridine (CUdR), in a similar manner to earlier investigations with the iodo- and bromo-analogues. The results are shown in Table 2. This compound presents less similarity to the normal precursor, thymidine; the size of the chlorine atom is somewhat smaller than the methyl group which it replaces[6]. Direct toxicity of the drug on reproductive capacity of these tumour cells was observed at the low dose of 100 mg/kg day × 4 days, in contrast to results with BUdR, where toxicity appeared at 300 mg/kg/day and IUdR, where no significant difference between control and drug-treated tumour cells was noted at a dose of 500 mg/kg/day × 4 days. With CUdR, additivity of radiation and drug effect was noted in almost all groups, but no significant potentiation (as determined by comparing control TD_{50} irradiated TD_{50} with control plus CUdR TD_{50} irradiated plus CUdR TD_{50}) of the radiation effect was noted. This result is similar to that observed at higher drug dosages with bromodeoxyuridine[1].

Table 2. EFFECT OF COBALT-60 γ-RADIATION ON CELLS TREATED WITH 5-CHLORODEOXYURIDINE

Treatment	Mean TD_{50} Tumour cells/mouse	Surviving fraction
Control	2 5 (1·0–4·0)	
CUdR, 100 mg/kg/day, 4 days	4·3 (3·7–4·9)	
CUdR, 300 mg/kg/day, 4 days	5·3 (4·5–6·1)	
CUdR, 500 mg/kg/day, 4 days	4·8 (4·4–5·2)	
1,500 rads, ^{60}Co γ, anoxic, 115 rads/min	135	0·019
1,500 rads, ^{60}Co γ, CUdR, 300 mg/kg/day, 4 days	240	0 022
2,000 rads	490	0 005
2,000 rads CUdR, 100 mg/kg/day	350	0·012
2,000 rads CUdR, 300 mg/kg/day	1,000	0 005
2,000 rads CUdR, 500 mg/kg/day	1,200	0 004
3,000 rads	13,700	0·00018
3,000 rads CUdR, 100 mg/kg/day	32,900	0 00013
3,000 rads, CUdR, 500 mg/kg/day	32,000	0·00015

It has been shown that IUdR, and to a certain extent BUdR, can potentiate the effect of X-irradiation delivered under anoxic conditions on tumour cell reproductive capacity. High drug dosage with BUdR and CUdR at all dose-levels studied acted only additively with X-rays in the P–388 mouse leukæmia. The finding that incorporation of an amount of iododeoxyuridine into these tumour cells sufficient to cause major modification of the dose-response to X-rays fails to modify their response to densely ionizing fission-spectrum fast neutrons gives support to the surmise that these compounds act by rendering the DNA of cells containing them more fragile and hence liable to damage by single ionizing events less energetic or less numerous than those which ordinarily would result in the reproductive death of the cell.

We thank Mr. Robert Woodley, Biology Division, Brookhaven National Laboratory, for assistance in performing the fast-neutron irradiations described here.

Mechanism of X-ray Inhibition of the Sodium Pump in Human Erythrocytes : Adenotriphosphatase Activity of Stromata

PREVIOUS results have shown that X-irradiation of human erythrocytes decreases the active efflux of sodium (sodium pump)[1]. However, 890 rads and 4,450 rads, which are effective in inducing a 45 and 73 per cent decrease of the active sodium efflux, respectively, do not inhibit glycolysis nor produce any effect on concentration of adenotriphosphate in red blood cells[2]. The lack of inhibition of the cellular system furnishing energy to the ion pump led us to investigate the biochemical mechanism in the membrane which underlies the active movement of sodium across the membrane.

Dunham and Glynn[3] and Post *et al.*[4] have shown that the ATPase activity of human red cell stromata consists of two components. The first component does not require the presence of alkali metal ions and is not inhibited by cardiac glycosides. The second component, on the contrary, requires sodium and potassium and is inhibited by cardiac glycosides,

Table 1

† The basal medium of incubation was: *tris* buffer *p*H 7·05 (115 mM) ATP neutralized with *tris* before addition (1·5 mM); magnesium chloride (0·5 mM); cysteine (1 mM). The medium containing sodium and potassium was obtained by addition of sodium chloride (16 mM) and potassium chloride (16 mM) to the basal medium.

which inhibit the sodium pump without interfering with the glycolysis and ATP synthesis of the cell[5]. This second component of the ATPase activity of red cell ghosts is, therefore, intimately linked with the sodium pump.

Human red cell ghosts were prepared by Herbert's method[6]. The suspension of stromata was divided in two parts, one of which was X-irradiated by a Dermopan apparatus with beryllium window, operating at 50 kV and 25 m.amp with 1 mm aluminium as a filter. The thickness of the irradiated suspension was 0·3 cm. Dose-rate was 12·5 rads/sec. Measured amounts of the stromata suspension were incubated in small flasks containing pre-warmed solutions at 37° C in a water bath and shaken by a motor during the 45-min period of incubation. Blanks for medium and cells were run in parallel. At the end of incubation, ice-cold 6 per cent perchloric acid was added to the stromata suspensions (1 : 1) and, after spinning at + 4° C, orthophosphate was determined in the supernatants by King's method[7]. The ATPase activity was referred to the volume of erythrocytes. The volume of cells in the flasks was obtained by comparison of the hæmoglobin content of a known quantity of the original suspension with that of a standard hæmolysate obtained by lysing a known amount of cells packed by centrifuging at 1,500*g* for 1 h, in a known amount of water.

Table 1 shows that X-irradiation with 890 rads and 4,450 rads inhibits the ATPase activity of stromata which requires sodium and potassium by 48 and 70 per cent, respectively. After the same doses of X-rays the ATPase activity, which is not dependent on sodium and potassium, decreases only by 4 and 29 per cent, respectively. The ATP-splitting activity requiring sodium and potassium is, therefore, particularly sensitive to X-rays, and the magnitude of this inhibition is in agreement with the decrease of sodium active efflux. In fact, 890 rads and 4,450 rads induce a 45 and 73 per cent respective decrease of the sodium pump. These results show that X-rays interfere with the mechanism of the pump in the cell membrane.

The investigations of Hokin and Hokin[8,9] led to the hypothesis that the formation of orthophosphate from ATP by membranes is actually the result of a metabolic process which consists of two steps by which sodium is actively transported across the membrane. The first step, which is assumed to occur at the inner surface of the membrane, consists of two reactions:

$$\mathrm{ATP}^{\equiv} + \mathrm{DG} \xrightarrow{\text{DG-kinase}} \mathrm{PA}^{=} + \mathrm{ADP}^{=}$$

$$\mathrm{PA}^{=} + 2\,\mathrm{Na}^{+} \longrightarrow \mathrm{Na}_2 - \mathrm{PA}$$

and the second step on the other site of the membrane:

$$\mathrm{Na}_2 - \mathrm{PA} \xrightarrow{\text{PA-phosphatase}} \mathrm{DG} + \mathrm{HPO}_4^{=} + 2\,\mathrm{Na}^{+}$$

where DG = diglyceride and PA = phosphatidic acid. PA would thus act as the carrier for the active transport of sodium. Therefore, the inhibitory effect of X-rays on the ATP-splitting activity of stromata which requires sodium and potassium has to be seen as an inhibition of the metabolic cycle of the sodium carrier.

BIOLOGY

Capacity of Fragments of Leaf Primordia to produce Whole Leaves

For a number of years both microsurgical and sterile culture techniques have been brought to bear on problems of leaf development in the vascular plants. Among the phenomena which have been investigated is the elusive process of leaf determination whereby the pattern of leaf morphogenesis is imposed on tiny outgrowths or primordia on the flanks of the apical meristem. Partial isolation of younger primordia by variously placed vertical incisions has led, in some cases, to the development of centric leaves, that is, organs which are determinate in their growth, but radial rather than dorsiventral in their symmetry[1].

In the fern *Dryopteris*, such partial isolation may result in the development of the youngest three primordia as shoot buds, that is, outgrowths which are both indeterminate and radial[2]. Similarly, it has been found that in the fern *Osmunda cinnamomea* L. any among the youngest nine primordia may develop as shoots, and ultimately whole plants, after excision and explantation to a sterile nutrient medium of simple composition. The development of such explants into leaves increases in frequency in progressively older primordia, and the tenth (P_{10}) and all subsequent primordia have always given rise to leaves[3].

The sum total of these experiments would suggest that leaf determination is a progressive process, possibly involving several steps, and that once it has become irreversible it imparts to a primordium a considerable measure of autonomy in subsequent development. Cutter[2], using surgical methods, concluded that in *Dryopteris* determination coincides with the establishment in a primordium of a distinct apical cell. It has been demonstrated that no such correlation with the setting off of an apical cell exists in the determination of primordia in *O. cinnamomea*. Rather, evidence, which has been described in full elsewhere[3], derived from an examination of the early development of primordia after excision, has led to the postulation that the fate of a particular primordium might depend on its content of a specific leaf-forming substance at the time of excision. It was felt that a combination of surgical and cultural techniques might be used to test, and possibly to refine, this hypothesis.

Subdivision of leaf primordia and the explantation of fragments might reveal whether development as a leaf is dependent on some configuration of cells in the intact primordium. If fragments of primordia, which have not been irreversibly determined as leaves, can produce whole leaves then the concept of a leaf-forming substance operating within the primordium would receive support. A considerable number of such subdivisions have been carried out and the results of these studies will be published in full elsewhere. The purpose of this communication is to report the outcome of one series of experiments in which it has been demonstrated that fragments derived from the vertical longitudinal splitting of primordia have the capacity to develop as whole leaves.

The organism used in the work recorded here was *Osmunda cinnamomea* L. and the methods utilized are essentially those previously used in sterile culture of excised fern leaves[4]. Sterilization procedures consisted of a surface treatment of the whole bud in a 7 per cent (by weight) solution of 'Pittchlor' (a commercial product containing 70 per cent calcium hypochlorite, manufactured by the Columbia-Southern Chemical Co., Pittsburgh, Pa.). Starting with P_{10} (10th oldest primordium) leaf primordia down to P_4 were identified and split sagittally with micro-scalpels made from razor blade fragments. Left and right halves were excised and planted in separate 1-oz. square tablet bottles, coded so that they could be compared later, on a medium which contained a modified Knudson's solution of mineral salts[5], 2 per cent sucrose, and 0·8 per cent agar. A number of unsplit control primordia were also included in the experiment. The explants were maintained in a culture room for a period of about three months at a temperature of 24° ± 1° C and an illumination of 600 ft. candles supplied by a combination of cool white fluorescent tubes and incandescent bulbs.

Excised half primordia of leaves of *O. cinnamomea* are able to undergo growth and development in sterile nutrient culture to produce whole leaves. At the times of excision, the half primordia consisted of nothing more than small inverted half-cones of meristematic tissue, the largest and oldest of which was less than 1 mm in height. At the end of the three-month growing period, they have undergone sufficient growth and development to produce leaves which consist of a rather broad base which is surmounted by a pinna-bearing rachis. In spite of the trauma imposed by the micro-surgical techniques used, leaves were not produced any less frequently than in unsplit primordia.

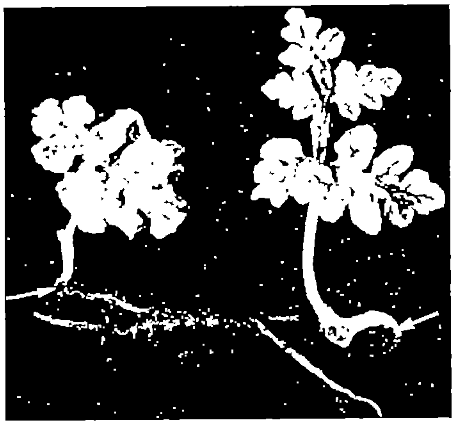

Fig. 1. Left and right halves of a split P_5 three months after excision. Each leaf has been turned 90° outward on its axis so that the scar of the longitudinal split (arrows) is visible. (× 3)

At the end of the three-month growing period, it is possible to take the left half and the right half of a particular primordium and to put these two halves together. In this way the two end-products may be compared closely and the developmental pattern of each of the original half primordia reasonably defined. This is possible throughout the series of primordia used in these experiments. Fig. 1 shows such a recombination of the halves of an original P_5 three months after excision. In most cases, although differences in size are common, the two halves of any primordium both develop either as leaves or as shoots. In a few instances, however, one half primordium produced a leaf while the other gave rise to a shoot. The development of a shoot from a half primordium corresponds closely to the pattern previously described for whole excised primordia[3].

Repeated observations of excised leaf primordia of *O. cinnamomea* have shown that it is possible to ascertain the original plane of dorsiventrality, even after considerable growth has occurred, from the position of the excision scar. It is important to be able to do this since the plane of dorsiventrality of a leaf produced by an excised primordium does not always correspond to that of the original explant. Half primordia from the older end of the series appeared to develop without any significant change from the plane of dorsiventrality of the original primordium. By contrast, halves of P_4 or P_5 give rise to leaves which face the scar of the longitudinal split (Fig. 1), suggesting that the plane of dorsiventrality has undergone a re-orientation.

It has been suggested that a leaf-forming substance contained within the primordium at the time of excision, rather than a specific structural pattern, may be responsible for the development of the primordium as a leaf. These experiments, which have shown that it is possible for a fragment of a primordium to produce a whole leaf, lend support to the idea of a leaf-forming substance rather generally distributed in the primordium. It is hoped that further work, including a detailed investigation of the stages of development of explanted leaf fragments of the type described in this report, together with an investigation of other types of fragments, will permit a better characterization of the process of leaf determination.

Mechanism of the 'Climacteric' Rise in Respiration in Banana Fruits

During the past 40 years various theories have been advanced to explain the large rise in rate of respiration, that is, the 'climacteric' rise, which accompanies ripening in certain fruits[1-8]; but no hypothesis has yet been accepted as proved.

We have used specific enzymatic methods[9-11] to determine the changes during the ripening of bananas (variety Lacatan) in the contents of fructose-6-phosphate, glucose-6-phosphate, fructose-1,6-diphosphate, phosphoenolpyruvate and malate. The changes in citrate and α-keto-acids (pyruvate, α-ketoglutarate and oxaloacetate) were estimated by conventional chemical methods. Associated with the 4- to 5-fold increase in rate of output of carbon dioxide during ripening, there was a 20-fold increase in the content of fructose diphosphate (Figs. 1 and 2) and increases of some 3- to 6-fold in the amounts of the α-keto-acids and of malate.

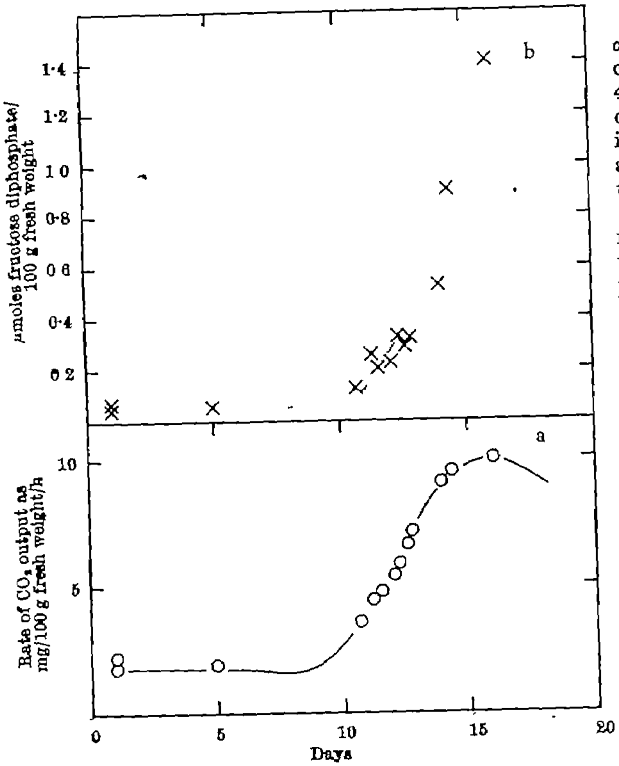

Fig. 1. *a*, The continuous line curve shows the change in rate of output of carbon dioxide of a single finger ripened at 18° C. The circles show the rates of respiration of other single fingers taken for analysis at different stages of ripeness. The circles are plotted with their respective rates on the continuous line so that the time scale for them is arbitrary. *b*, Changes in content of fructose diphosphate of the single bananas of which the rates of output of carbon dioxide are shown in Fig. 1*a*. The time-scale is that of Fig. 1*a*

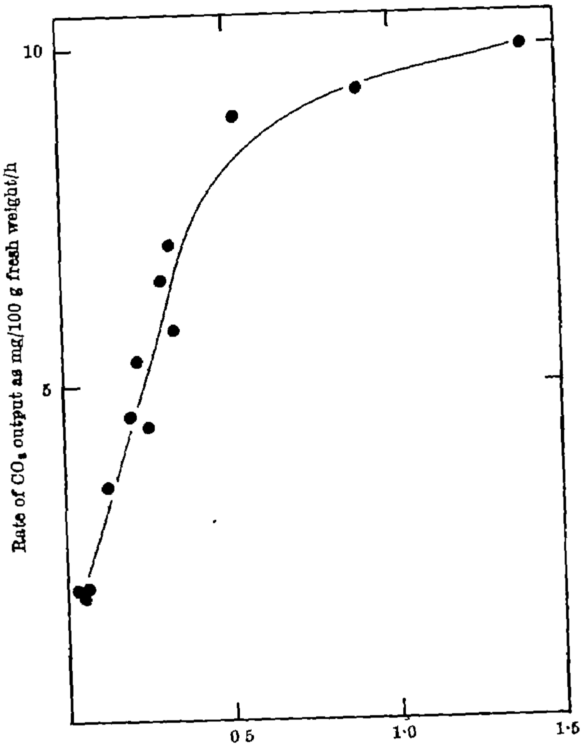

Fig. 2. Relation between rate of output of carbon dioxide and content of fructose diphosphate

The results support the view that the increase in rate of respiration during the 'climacteric' rise is due to the increase in the concentration of fructose diphosphate. Since the contents of glucose-6-phosphate and of fructose-6-phosphate were increased by only 2- to 3-fold, the rise in fructose diphosphate may be related to an activation of phosphofructokinase as suggested for animal muscle[12].

Treating bananas with ethylene induced changes of the same pattern as those mentioned here.

Room-Temperature Storage of Coconut Pollen

Pollen introduction and exchange have been suggested as a means of broadening the scope of breeding programmes designed to produce disease-resistant and high-yielding coconuts[1-3]; and at a recent meeting of the Food and Agriculture Organization Technical Working Party on Coconut Production it was stressed[4] that the most important material question to be solved concerned the mode of transportation of pollen. It is clear that present methods of storage of coconut pollen[5-8], though useful, are inconvenient for routine pollen exchanges over long distances.

J. R. King[9-11] has reported prolonged room-temperature storage of freeze-dried pollens in sealed containers under an inert gas, and more recently under vacuum[12]; and early results of work on storage and dispatch initiated in this Department show that coconut pollen similarly treated can be stored for long periods at room temperature.

In one experiment, unopened male flowers from inflorescences of six 'Jamaica tall' palms (A–F) were placed in separate newspaper envelopes and oven-dried at 40° C (for approximately 2 days). Pre-treatment in this way has resulted in greatly increased quantities of pollen[13]. Initial pollen viability estimates were made from counts of at least 400 grains after germination on a sucrose gelatine medium (10 per cent sucrose, 10 per cent gelatine).

The equipment used for freeze drying consisted of a 6-port ampoule header connected by a U-tube to a high-vacuum pump. Ampoules containing pollen were attached and pre-frozen by immersion in dry ice and acetone before drying under vacuum (2–5 mm mercury). The U-tube surrounded by freezing mixture served as a moisture trap.

Duplicate batches of 6 ampoules after 3 h freeze drying were heat-sealed under vacuum.

After one month's storage at room temperature, samples A_1, B_1 and C_1 were opened and viabilities estimated immediately, after 2 and 4 h, and after one day at relative humidity 70 per cent. Samples from D_1, E_1 and F_1 were similarly tested after two months and replicates D_2, E_2 and F_2 were then packed in light-weight polystyrene containers and separately dispatched on a round trip to New Guinea. Viability was again tested *in vitro*, approximately 4 months after collection. The results obtained are given in Table 1.

The results show that freeze drying is a workable technique for the treatment of coconut pollen, since viability obtained after prolonged room temperature storage is in excess of that normally required for pollination. Further samples A_2, B_2 and C_2 still remain to be tested at 6 months, and the results of a number of controlled pollinations and further experiments to determine the optimum period of freeze drying will be reported later.

Table 1. VIABILITY ESTIMATES OF FREEZE-DRIED COCONUT POLLEN AFTER STORAGE AT ROOM TEMPERATURE

Sample	Initial viability (%)	Storage period	Viability per cent. Pollen tested after different periods at room temperature and 70 per cent relative humidity* 0	2 h	4 h	Approx. one day
A_1	82	1 month	18	16	12	12
B_1	49	,, ,,	7	14	10	10
C_1	83	,, ,,	nil	9	8	6
D_1	80	2 months	51	51	42	31
E_1	66	,, ,,	34	35	33	35
F_1	34	,, ,,	30	22	18	22
D_2	80	4 months	2	14	21	—
E_2	66	,, ,,	27	22	31	—
F_2	34	,, ,,	20	24	23	—

*Preliminary experiments indicated improved viabilities after 2 and 4 h.

The ability to store coconut pollen for prolonged periods at room temperature will be an asset to coconut breeding and seed production, and, in particular, will facilitate introduction and exchange.

I thank Dr. J. L. Plummer, of the University College of the West Indies, for help with the freeze-drying technique. Thanks are also due to Mr. T. A. Jones, director of this Department, for advice, to Mr. A. E. Charles of the Department of Agriculture, Keravat, New Britain, in the Territory of Papua and New Guinea, who co-operated by labelling and returning the samples, and to Mrs. M. Hall for technical assistance with the pollen viability tests.

A Technique for inoculating Wheat with Rusts for Glass-house and Test-tube Culture

The conventional method of inoculating wheat with rusts is to plant wheat seed in pots in a glass-house and smear the first leaf with spores of rust when the seedlings are 6–7 days old. The pots are incubated for 24 h in a moist chamber and then transferred to the benches of the glass-house. This technique takes about 15–20 days from the date of seeding to the date of the appearance of the rusts, depending on the species of the rust, temperature and light conditions in the glass-house being favourable for the development of the different species of the rusts.

For inoculating wheat with rusts by this technique for glass-house and test-tube culture, wheat seeds are germinated in a Petri plate on a moist filter paper in a room. After 60–72 h, when the plumule has grown about half an inch, the seed is picked up by hand. Meanwhile, a spore suspension of rust is made in sterile water containing a trace of detergent. Using a fine needle in a hypodermic syringe, the spore suspension is injected a little above the point from where the plumule and radical are differentiating. The test of successful inoculation is the appearance of a drop or the ejection of a fine squirt of water from the tip of the plumule. If this drop is taken on a slide and examined under the microscope, it will be found to contain the rust spores. With a little practice, it is possible to inoculate about

120 seedlings in 1 h with 3–4 ml. of the spore suspension.

The inoculated seedlings are then transplanted in 6-in. pots in the glass-house and irrigated with water. Leaf and stem rusts appear after 7 and 10 days respectively from the date of transplant on the first leaf with 100 per cent infection in the seedlings.

To obtain the culture of rust in a glass test-tube by this technique, the inoculated seedling is transferred to a glass test-tube containing 10 ml. of 0·5 per cent water agar. A few drops of water are added to the surface of the agar to maintain good humidity in the tube. The tubes with open mouth may be kept in the glass-house or in a room receiving direct sunlight. The seedling continues to grow in the tube and rust pustules appear on the first leaf, and in some cases on the second, third and fourth leaf, as well as on the first tiller.

Occurrence of Unusual Bodies in a Marine Pennate Diatom

DURING an investigation of the marine phytoplankton in a shallow Rhode Island coastal salt pond[1], an abundant benthic diatom flora occurred throughout the water column on May 3, 1961. This community was probably roiled up from the bottom during the vertical mixing characteristic of the water-mass at that time (Table 1); a distinct halocline persisted prior to this date. The water-mass was 1·5–2·0° C warmer than in mid-April and while the bottom (6 ft.) salinity decreased by 2·5 parts per thousand, the mean water-column salinity decreased by only 1 part per thousand. Similarly, gross changes were not observed in other environmental factors studied: dissolved oxygen, nitrate, nitrite, silicate and phosphate.

Table 1. PHYSICAL CONDITIONS AND PENNATE DIATOM ABUNDANCE ON MAY 3, 1961

Depth (ft.)	*Gyrosigma* sp. cells/l.	All pennate diatoms cells/l.	Temp. (°C.)	Salinity (‰)	Density σt
0	360	255,000	9·2	26·42	20·41
3	440	235,000	8·7	26·55	20 58
6	2,600	210,000	8·7	26·60	20·68

Included among these tychopelagic diatoms was the sudden appearance of a *Gyrosigma* sp., represented almost exclusively by empty, broken frustules and moribund individuals in the preserved 52-ml. samples examined microscopically from each depth in the phytoplankton census. One intact specimen was encountered, however, which differed from the other *Gyrosigma* specimens and all other pennate diatoms previously examined. This specimen contained 200–250 spherical, green bodies measuring 3·5–7·5μ in diameter, and distributed in a random, though clumped, manner throughout the intact cell. The periphery of these bodies was slightly thickened. Neither flagella, pyrenoids nor a nucleus were observed. Apart from these bodies, the specimen was devoid of its usual complement of cytoplasmic material and chromatophores.

Subdivision of the protoplast into atypical, non-flagellated bodies has been observed in three other species of pennate diatoms[2–4]. Recently, the occurrence of biflagellate swarmers within the cells of the marine pennate diatom *Amphiprora hyperborea* has also been reported[5]. However, the *Gyrosigma* bodies in no way resembled the *Amphiprora* swarmers. While they did possess a somewhat thickened wall, their general structure and number suggest that they were not similar to the spore-like bodies noted in the limnetic pennate *Surirella spiralis*[2]. Kolbe[4] observed the frequent occurrence of 6–16 naked, pigmented, pyrenoid-containing bodies in motile specimens of the brackish water pennate *Nitzschia vitrea*. He concluded that these rounded, pigmented bodies were formed by subdivision of the chromatophores, a phenomenon he designated as 'Hypertomie'. Kolbe suggested this might also be the origin of similar bodies observed in the limnetic diatom *Eunotia lunaris*[3]. The green pigmentation of the *Gyrosigma* bodies suggests a possible derivation from the original cell chromatophores, but their lack of a pyrenoid and great abundance distinguish them from those observed by Kolbe. Finally, the *Gyrosigma* bodies were morphologically distinct from the microspores commonly observed in centric diatoms[6].

While the *Gyrosigma* bodies bear certain resemblances to the non-flagellated bodies noted on rare occasions in other pennate diatoms, they appear to represent a new type. It is unknown whether they represent a reproductive stage of the life-cycle, an unusual decomposition of a moribund specimen, or are symbionts. The nature and function of the unusual bodies reported in the other pennate diatoms also remain an enigma[5,7].

ENTOMOLOGY

Laboratory Colonization of the Horn Fly, *Hæmatobia irritans* (L.)

THE horn fly is a blood-sucking insect (*Hæmatobia irritans*) the only host of which, for all practical purposes, is cattle. The adult remains on cattle almost continuously, leaving momentarily to lay eggs in the freshly dropped fæces. Horn flies have been reared on a caged steer at Kerrville since 1947, but it was only in 1961 that this colony could maintain itself without the addition of field-collected flies. Some attempts at colonization of horn flies away from a bovine host have been briefly reviewed by McLintock and Depner[1]. Many workers have reared adults from the egg stage and maintained the flies on laboratory diets (citrated bovine blood) but the production of fertile eggs has not been reported. On the theory that micro-organisms in citrated bovine blood were detrimental to the flies and/or that bovine blood did not contain all the essential nutrients for reproduction, a series of laboratory diets was tested. Flies taken as pupæ from the caged-steer colony were fed bovine blood containing antibiotics, and attempts were made to fortify the blood with other materials. These experiments led to the establishment of a laboratory colony that reproduced without contact with a host.

For each test diet, 480 ml. of blood was drawn from a steer into a vacuum transfusion bottle containing 120 ml. of ACD* anticoagulant solution. The blood was mixed immediately with the other ingredients and the unused portion stored under refrigeration. For each test diet, 10 male and 10 female flies were placed in a cylindrical plastic cage about 3 in. tall and 1½ in. in diameter, covered at bottom and top with light-weight unbleached muslin. To avoid handling the flies, each cage was fitted horizontally with a sliding sheet-metal divider so that the flies could be trapped in one part of the cage while the other part was cleaned. The flies fed through the muslin cover from absorbent cotton pads soaked in the diet mixture and placed on top of the cage. The top of the cage was covered with a plastic dish to retard evaporation. The pads were usually replaced twice a day; once a day the cage was cleaned and the muslin covers changed. If eggs had been laid, they were collected at cleaning, placed on moist paper towelling in a vial, and held at 80° F for hatching. The cages used for colony rearing were similar, except that they were 6 in. in diameter and the bottoms were made of plastic screen, which was placed over cow manure on which the flies could oviposit. The manure was collected fresh and frozen for a few days to avoid insect contamination.

The reproduction data obtained with some representative diet mixtures are presented in Table 1. The first diets tested were blood only and blood in combination with various antibiotics. The best results were obtained with 1 mg streptomycin plus 1,000 units penicillin plus 250 units mycostatin/ml. of diet (referred to in Table 1 as 'standard antibiotic mixture'). Flies receiving blood plus this antibiotic mixture lived longer, but very few viable eggs were laid.

Table 1. REPRODUCTION OF HORN FLIES FED LABORATORY DIETS (10 MALES AND 10 FEMALES PER TEST)

Diet mixture	No. of eggs laid	Percentage of hatch
Flies held at 80° F		
1 part blood, 1 part beef juice + 1 mg streptomycin and 250 units mycostatin/ml.	199	16
Flies held at 90° F		
1 part blood, 1 part beef juice + 1 mg streptomycin and 250 units mycostatin/ml.	874	25
Blood only	182	13
Blood + standard antibiotic mixture	139	25
4 parts blood, 1 part physiological saline + standard antibiotic mixture + 20 mg yeast extract/ml.	248	45
1 part blood, 1 part beef juice	228	17
1 part blood, 1 part beef juice + standard antibiotic mixture	793	40

The next ingredient added was 'beef juice', a liquid obtained by centrifuging fresh ground beef muscle tissue for about 15 min at 3,000 r.p.m. When a diet of 1 part blood, 1 part beef juice, and the standard antibiotic mixture was fed, sufficient viable eggs were obtained to keep the colony in existence for five generations, although numbers did not increase from one generation to the next. Until the sixth generation the flies were held at 80° F. On the same diet, but with the temperature at 90° F, the number of flies increased from 125 in the sixth generation to 887 in the seventh, and the preoviposition period decreased from 6 to 4 days after eclosion. With testing and rearing conducted at 90° F, the colony, now in its tenth generation, is flourishing. Differences in the number of eggs laid and percentage hatch when the flies were reared at the two temperatures are shown in Table 1.

Continuous fluorescent lighting was used for testing and rearing. The humidity was not controlled, but because the cages were enclosed by plastic dishes covering the moist blood pads, humidity inside the cages was probably higher than that in the room.

Several materials more readily available in standardized form than the centrifuged beef juice, notably a commercial yeast extract and a prepared beef extract formulation, have been tested as alternative additions to the blood and antibiotics, but none has proved superior in promoting reproduction.

I thank R. E. Gingrich for advice on insect nutrition and E. D. Frazar for design of the cages.

Effect of Phenylthiocarbamide on Viability of *Drosophila melanogaster* Strains with High and Low Tyrosinase Activity

Kroman and Parsons[1] have reported that the mutant ebony, *e*/*e*, in *Drosophila* is less viable than *e*/+ and +/+ on medium containing phenylthiocarbamide (PTC). They suggest[2] that poor viability of *e*/*e* on PTC medium may be correlated with the low tyrosinase activity reported for this genotype[3]. Experiments were performed to test this suggestion using several other strains of flies, and the results indicate that factors other than those associated with low *in vitro* tyrosinase activity account for poor viability on medium containing PTC.

Siblings were allowed to lay approximately 100 eggs in vials on normal medium containing 0·04 per cent PTC (experimental) and on normal medium (controls). For each strain tested, there were 7–10 experimental vials and 3–8 control vials. Cultures were maintained at 25° C. and were observed daily. In no case did PTC in the medium interfere with egg-laying or with hatching. In all instances development on the PTC medium was delayed after the first instar stage. All cultures which developed to the third instar stage gave rise to viable adults; in cultures from which no adults emerged, all individuals had died before the third instar stage. Adult survivors eclosed several days later and were smaller in size and in number than in control cultures.

The results are shown in Table 1. Activity is reported in DOPA oxidase units[4] since DOPA is the

Table 1. VIABILITY OF VARIOUS STRAINS OF FLIES ON MEDIUM CONTAINING PTC

convenient substrate used in routine assay, but the same relationship holds when tyrosine is used as substrate. The results indicate that fitness of flies raised on PTC medium is not related to the level of tyrosinase activity which has been found to be characteristic of these lines[4]. PTC inhibits tyrosinase activity *in vitro* by combining with the copper atoms of tyrosinase molecules. Perhaps the failure of strains 1, 2, 4 and 6 to survive on PTC medium may be due to low levels of other copper-requiring enzymes, whereas strains 3, 5, 7, and 8 may have high levels of other copper enzymes. A second possibility is that tyrosinase essential for a critical second instar process may not be quantitatively related to *in vitro* measurements in extracts of adults.

Pyridoxine Requirements of *Agria affinis* (Fall.)

House[1], using a chemically defined diet and aseptic rearing technique, showed that larvæ of the parasitic dipteron, *Agria* [= *Pseudosarcophaga*] *affinis* (Fall.), would grow on an apparently pyridoxine-free diet. Recent reviews of Levinson[2], Lipke and Fraenkel[3], Friend[4], and House[5] indicate that *A. affinis* is peculiar in this respect.

There are several possible explanations for this peculiarity: House's diet may contain some impurity with vitamin B_6 activity; sufficient vitamin may be carried over from the female parent for one generation; the larvæ may be able to synthesize the vitamin; or pyridoxine or its derivatives may play no part in the metabolic processes of the insect. In the work recorded here these possibilities were limited by analysing the diet and larvæ for vitamin B_6 and by comparing the effects of lack of the vitamin on the transaminase systems of *A. affinis* and *Musca domestica* L., which last, as House and Barlow[6] found, will not pupate when grown on essentially the same deficient medium.

Agria affinis were obtained from a colony maintained on pork liver[7], and *Musca domestica* L. from a colony maintained on Richardson's[8] medium. Techniques of aseptic rearing were described by House[9] and the basic chemically defined diets by House and Barlow[6,10] for *A. affinis* and *M. domestica*, respectively. Vitamin B_6 analyses were performed for us by the Vitamin and Nutrition Section of the Department of National Health and Welfare, Tunney's Pasture, Ottawa, using *Saccharomyces carlsbergensis* 4228. Nitrogen analyses by Lang's micro-Kjeldahl method[11], and glutamic-oxalacetic transaminase determinations by the method published by the Sigma Chemical Co.[12] were performed on homogenates of whole larvæ.

All means are given with their standard error; differences between means are compared by t tests and are taken to be significantly different when $P < 0{\cdot}05$.

The vitamin B_6 assays were not precise because the amount of material which could be supplied was small: the very young larvæ dissected from gravid females and the larvæ reared individually on the supposedly pyridoxine-free diet were scarcely sufficient for a single determination. It can only be said that there was sufficient vitamin B_6 activity in the diet to account for several times its increase in the larvæ during growth.

The comparison of the effects of the pyridoxine-free diet on transamination in *A. affinis* and *M. domestica* brought out the following facts. First, there is a significant difference in transaminase activity between larvæ of the two species taken from their colonies. House-fly larvæ contained 29·9 ± 3·7 and *A. affinis* 20·9 ± 3·1 U/mg wet weight. There is little probability that this was due to a difference in metabolically active tissue because the nitrogen contents of the two species were the same (4·2 ± 0·3 per cent). Thus the enzyme activities based on nitrogen content, 0·49 ± 0·07 U/μg nitrogen for *A. affinis* and 0·71 ± 0·13 U/μg nitrogen for *M. domestica*, were still significantly different. Second, chemically defined diets are far from nutritionally adequate, judged on the proportion of nitrogen in the larvæ. Reared on the chemically defined diet with pyridoxine, *A. affinis* larvæ were only 0·66 ± 0·14 per cent nitrogen and *M. domestica* larvæ 0·94 ± 0·15 per cent. Lack of pyridoxine did not alter the nitrogen content. With the reduction in nitrogen there was a smaller reduction in transaminase so that it was somewhat higher than in stock-reared larvæ, on the basis of nitrogen content, *A. affinis* having 1·33 ± 0·32 U/μg nitrogen, *M. domestica* 0·84 ± 0·07 U/μg nitrogen. Third, lack of pyridoxine reduced transaminase contents significantly in both species, but most seriously in *M. domestica*. In this species the transaminase-level fell from 0·84 ± 0·07 to 0·30 ± 0·06 U/μg nitrogen; in *A. affinis* the decrease was from 1·33 ± 0·32 to 0·96 ± 0·34 U/μg nitrogen.

It is curious that larvæ reared on the chemically defined diet increased in size though the concentration of nitrogen in their bodies was thereby reduced to about one-sixth that of larvæ from the colony and that they were able to develop into an adult under such conditions. As the larvæ grow and develop while their nitrogen concentration is decreasing, the latter would be the best criterion for improving the diet until these larvæ are similar to stock-reared larvæ. Rate of development and/or an increase in total weight are probably the criteria that have been used most in nutritional studies. Though De Groot[13], Sedee[14], and others used nitrogen content, Sedee found that the nitrogen content of *Calliphora erythrocephala* (Meig.) corresponded so well with their dry weights that the nitrogen determination was discontinued. Apparently, no one has used nitrogen concentration, which would seem to be the most valuable criterion in this case.

It is now possible to draw some limited conclusions with regard to the pyridoxine requirement of *Agria affinis*. First, the supposedly pyridoxine-free diet contains enough impurity with vitamin activity to account for the accumulation of pyridoxine during growth. No assumption need be made of vitamin carried over from the female parent, of synthesis of the vitamin, or of lack of a metabolic role for it. Indeed, the results show that a dietary supply of pyridoxine is required to maintain the level of transaminase activity. Although lack of pyridoxine is not a growth-limiting factor for *A. affinis* reared on the present chemically defined diet, it could be so if protein metabolism were improved.

The fact that *M. domestica* larvæ, to develop, require additional pyridoxine in this diet while *A. affinis* do not, indicates an important difference between these species. Perhaps the form of the vitamin present in the 'pyridoxine-free' diet is usable by *S. carlsbergensis* and *A. affinis* but not by *M. domestica*; such differences have been reported[15]. Alternatively, *A. affinis* may be able to sequester the vitamin more efficiently than *M. domestica.* It is axiomatic that metabolic differences between animals are as great as the morphological differences generally used in taxonomy. Exploitation of these could lead to development of insecticides as discriminating as taxonomy. Evidence of this is already present in the development of chemotherapeutics, antibiotics, fungicides, and herbicides with specificity of a broad nature, and each instance of such metabolic differences deserves extensive investigation.

I thank Drs. J. A. Campbell and J. M. McLaughlan, and their associates of the Vitamin and Nutrition Section of the Department of National Health and Welfare, Tunney's Pasture, Ottawa, Ontario, Canada, for their co-operation in performing the vitamin B_6 assays for this investigation.

MICROBIOLOGY

Ability of a *Vibrio* grown on Benzoate to oxidize *para*-Fluorobenzoate

THE utilization of aromatic compounds by micro-organisms for growth in mineral-salts media is well established; pathways by which such substances are broken down by micro-organisms have been recently reviewed[1]. A number of micro-organisms can also use halogen-substituted organic acids as growth substrates in mineral-salts media[2], the organically bound halogen being liberated as the halide ion during growth. An enzyme preparation, obtained from a pseudomonad grown in the presence of monochloroacetate, has been described[3] which catalyses the conversion of monochloroacetate into glycollate and chloride ions.

In this communication we would like to point out that the possibility exists that a micro-organism, grown in the presence of a non-halogenated aromatic acid, may be capable of metabolizing, albeit partially, simple halogen analogues of the aromatic growth substrate. Similar situations with regard to normal metabolites and simple halogen, especially fluorine, analogues are well known. For example, the synthesis of a monofluorocitrate from monofluoroacetate (for review see ref. 4), the synthesis of monofluoromalate from monofluoroacetate involving the enzyme malate synthetase[5,6] and the synthesis of bacterial cell-wall mucopeptide precursors linked to 5-fluorouracil instead of uracil[7].

Vibrio 01 (ref. 8) can be grown readily (for example, overnight) at 30° C with forced aeration, in a medium composed of sodium benzoate 0·005 M; potassium dihydrogen phosphate, 2 g; ammonium sulphate, 1 g; crystalline magnesium sulphate, 0·4 g; distilled water, 1 litre; and sufficient sodium hydroxide to adjust the initial *p*H of the medium to 7·2. The crystalline magnesium sulphate was added aseptically to the rest of the medium after *p*H adjustment and sterilization. No growth occurred over a period of 48 h in a medium in which an equimolar amount of *p*-fluorobenzoate was substituted for benzoate, even when such a medium was inoculated with cells previously adapted to benzoate.

Washed suspensions of benzoate-grown cells will, however, oxidize *p*-fluorobenzoate, typical results being shown in Fig. 1. In the case of benzoate, oxygen uptake greater than that in the endogenous ceases after the uptake of about 11 atoms of oxygen per mole of benzoate initially present; with *p*-fluorobenzoate as substrate, the corresponding figure is 8–9 atoms of oxygen. In contrast *p*-chlorobenzoate and *p*-bromobenzoate are but slightly oxidized, 1 atom of oxygen per mole of substrate initially present being taken up in each case. The *m*-fluoro analogue (not shown in Fig. 1) is oxidized much more slowly than *p*-fluorobenzoate by benzoate-grown cells with the uptake of about 2 atoms of oxygen per mole of substrate initially present.

Using the zirconium-alizarin method, as described by Feigl[9], fluoride ions could be detected in reaction

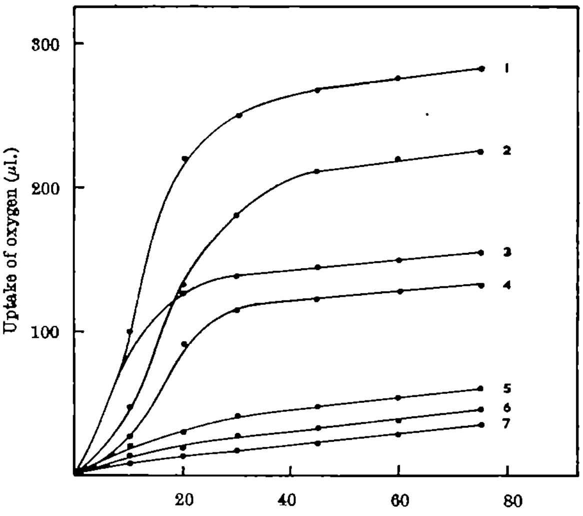

Fig. 1. Oxidation of various substrates by washed suspensions of *Vibrio* 01 grown with benzoate. Conventional Warburg apparatus was used, each flask contained 0 2 ml. (20 per cent w/v) potassium hydroxide in the centre well, and 1 ml. of bacterial suspension and phosphate buffer, *p*H 7·2, to a total volume of 3 ml Side bulbs contained: (1) 2 μmoles benzoate; (2) 2 μmoles *p*-fluorobenzoate; (3) 1 μmole benzoate; (4) 1 μmole *p*-fluorobenzoate, (5) 2 μmoles *p*-chlorobenzoate; (6) 1 μmole *p*-chlorobenzoate; (7) endogenous. The oxidation of *p*-bromobenzoate (2 μmoles and 1 μmole) is practically identical to (5) and (6) respectively

mixtures at the end of experiments in which cells had been oxidizing *p*-fluorobenzoate. In order to obtain some quantitative data on the amount of free fluoride produced, four flasks were set up (*A*, *B*, *C* and *D*) each containing 0·015 M phosphate buffer, *p*H 7·2; *A*, *B* and *C* contained both *p*-fluorobenzoate and benzoate at final concentrations of 0·002 M and 0·001 M, respectively. *D* contained benzoate but none of the fluorobenzoate. Washed benzoate-grown cells, collected from a fully grown 1·5-litre culture, were resuspended in 30 ml. of phosphate buffer, this suspension being divided into three 10 ml. portions. Flask *A* was inoculated with one portion, flask *D* with another; the third portion was heated at 56° C for 30 min and then added to flask *B*. No cells were added to flask *C*. The final volume in each flask was 100 ml. The contents of all flasks were strongly aerated at 30° C. After 3 h, cells were removed from the contents of each flask by centrifuging; the supernatants were then analysed for their free fluoride content[10]. Phosphates, which interfere in this method, were first removed by precipitation as the silver salt by adding sufficient half-saturated silver nitrate solution; excess silver ions were removed by adding the minimal amount of a 0·1 per cent (w/v) sodium chloride solution. Precipitates of silver phosphate and silver chloride were removed by centrifuging.

Free fluoride ions were detected in the supernatant obtained from flask *A*, the amount liberated being 60–65 per cent of the organically bound fluorine initially present. No fluoride ions could be detected in the supernatants obtained from flask *B* (inoculated with heat-treated cells), from flask *C* (uninoculated) or from flask *D*, which contained no *p*-fluorobenzoate.

Production of Opacity in Egg-Yolk Medium by *Listeria monocytogenes*

SEVERAL micro-organisms are known to cause opacity when growing in fluid or on solid culture media containing native, non-heated egg-yolk[1–13]. This egg-yolk reaction can help in the classification of the bacteria and in some species it is associated with the virulence (especially toxicity) of the organisms. We have observed that *Listeria monocytogenes* strains regularly produced opacity in egg-yolk agar medium hitherto not reported in the literature.

Testing 50 strains of *Listeria monocytogenes* on egg-yolk agar plates (with 5 per cent non-heated, native egg-yolk content) after an incubation of 6 days at 37° C all the strains produced opacity in the medium. Two forms of reaction by the egg-yolk were observed. The majority of the strains (45) caused only slight opacity in the medium under and around the macrocolonies with a weak or marked clearing in the centre of the zone. The remaining 5 strains, on the other hand, formed strong and dense precipitates in the medium without clearing like the strains of *B. cereus*.

These characteristics showed no tendency to vary during an observation period of one year and remained stable even after serial transfers on egg-yolk agar plate. The cultures seemed to be homogeneous in this respect, as no aberrant colonies could be detected after examining thousands of isolated colonies of each strain. No correlations between the serotype, age, origin of the strains and the egg-yolk reaction type have been found. The only pattern was the hæmolytic activity, which showed some agreement with the egg-yolk reaction characteristics. All *Listeria* strains producing strong precipitate in the egg-yolk medium were strongly hæmolytic on blood-agar plate. The weak opacity producers exerted generally weak hæmolytic activity; only two strains caused marked hæmolysis on blood-agar plate.

The egg-yolk reaction in different bacterial species is often associated with phospholipase (lecithinase, cephalinase) activity; in other cases lipase action or proteolysis have been suggested as the cause of the disturbance in the stability of the medium[9,14,15]. The reactions produced by *Listeria* strains are due to the action of macromolecular substances, probably enzymes, since the changes failed to develop when the strains were cultured on egg-yolk agar plate covered with a sterile 'Cellophane' membrane. Further investigations are in progress to elucidate the mechanism of the egg-yolk reactions in *Listeria monocytogenes* strains and to examine the probable role of these characteristics in the virulence.

Susceptibility of *Proteus mirabilis* and its Stable *L*-Forms to Erythromycin and Other Macrolides

Proteus spp. and other Gram-negative rods have been reported to be highly resistant to macrolides[1], but nothing is known about the mechanism of this natural resistance. Using *Proteus mirabilis* I have compared the susceptibilities of the normal bacillary forms and the so-called stable *L*-forms. The latter are distinguished by the absence of the cell walls of the parent strain. The absence has been demonstrated by the lack of phage receptors[2,3] and by chemical analysis[4]. In this respect they are similar to the protoplasts of Gram-positive bacteria produced by the action of lysozyme[5]; but, unlike these, they are able to grow well on solid media and may also be adapted to cultivation in broth. Like protoplasts, however, they do not revert to the normal rod forms, but grow indefinitely as *L*-forms even in the absence of penicillin, which was used for their induction in the first place.

Earlier studies on the susceptibility of *L*-forms to antibiotics were made by Ward *et al.*[6] and other workers[7]. However, in most cases use was not made of stable *L*-forms but rather the unstable *L*-forms or spheroplasts or mixtures of these forms, all of which possess cell walls or fragments thereof. With *Proteus mirabilis* it is possible to investigate the behaviour of the cell as a whole and of the 'cell contents' (protoplast) in the presence of substances such as antibiotics.

In my experiments, erythromycin, carbomycin (magnamycin), spiramycin, oleandomycin, leucomycin and angolamycin were tested by an agar diffusion method using double-layer plates, the upper layer being inoculated with either the normal rod forms or the stable *L*-forms. The antibiotics were added to holes (0·05 ml.) to produce zones of inhibition after diffusion. The concentrations of the test solutions were 1,000, 100, 10 and 1 μg/ml. Table 1 shows the results.

Table 1. ACTION OF MACROLIDES ON *Proteus mirabilis* (STRAINS VI AND 52) AND THEIR STABLE *L*-FORMS

(Figures represent the minimal inhibitory concentrations in μg/ml.)

	VI	52	*L*-form VI	*L*-form 52
Erythromycin	≈ 1,000	≈ 1,000	< 1	< 1
Magnamycin	> 1,000	> 1,000	< 1	< 1
Leucomycin	> 1,000	> 1,000	< 1	< 1
Spiramycin	> 1,000	> 1,000	< 10	< 10
Oleandomycin	> 1,000	> 1,000	< 10	< 10
Angolamycin	> 1,000	> 1,000	< 10	< 10

It can be seen that the macrolides act selectively on the stable *L*-forms while the parent strains are virtually unaffected.

For comparison, some other antibiotics have been tested by the same method. Netropsin, neomycin, kanamycin, paromomycin, streptomycin, novobiocin, chloramphenicol, chlortetracycline and oxytetracycline inhibited at relatively high concentrations both the bacillary forms and the *L*-forms, the latter being commonly slightly more sensitive. Grisein and actidione, as well as mycostatin, trichomycin and some other polyene antibiotics, did not affect any of the forms of *Proteus*.

The strikingly selective action of the macrolides as a group may be due to the absence of the cell walls in the *L*-forms. In contrast to many other antibiotics, the molecules of these drugs are evidently prevented by the walls from freely entering the cell contents of the normal rod forms. It is unlikely that the observations can be explained by basic differences in the metabolism of *Proteus* and its *L*-forms because the reactions so far investigated have been shown to be essentially the same[4]. Furthermore, the possibility of selective enzymatic inactivation of the macrolides by the rods was excluded—prolonged incubation of the antibiotics with *Proteus* rods did not lead to specific loss of activity.

It is suggested that within the commonly used range of concentrations the marked natural resistance of *Proteus mirabilis* to macrolides is due to the inability of the substances to penetrate the cell walls of the normal rods in effective amounts and is not due to insensitivity of the metabolism of *Proteus*.

PSYCHOLOGY

Counter-injection: a New Technique for the Analysis of Drinking

A METHOD of regulating separately the sensory and osmotic or other physiological factors in ingestion is of importance in the analysis of satiation and reward. Oesophageal fistulation has frequently been used for this purpose; but it removes many of the sensory consequences of ingestion in the upper intestinal tract along with the elimination of absorption factors. Further, the animal after the operation, which is difficult in small animals, cannot feed normally and is not easy to maintain in a good state of health. Preloading has also been reported; but one of the disadvantages of this method is that it introduces critical delays between the preload and actual drinking.

Briefly, the technique described here is to inject into the stomach by way of a chronically implanted fistula small quantities of fluid (such as hypertonic saline) in proportion as the animal itself drinks, say, water. In this way, the tonicity of the fluid arriving in the animal's stomach can be rigidly controlled, however much the animal drinks of some other concentration. So far we have used this technique to make water drunk by the rat result in a slightly hypertonic saline in its stomach.

This method requires a precise means of regulating the amount of saline injected into the stomach with respect to the amount of water being ingested by the animal. To accomplish this, a simple experimental technique was developed and tested. Drinking took place in a round wire cage with a plastic cover; the animals were tested singly and were required to lap a glass nozzle through a hole in the plastic top. Each lap activated the relay of an electronic drinkometer, a more sensitive development of the one described by Hill and Stellar[1]; this relay, in turn, activated the stepping motor of a Davis vertical liquid pump, fitted with a 50-c.c. syringe filled with water. As the motor advanced with each lap of the rat, water was pumped from the syringe through a piece of polyethylene tubing down into the drinking nozzle; the pump motor was so regulated that, with each lap of the rat against the nozzle, a lap's worth of water was deposited on its tongue. Furthermore, the pumping apparatus was modified in the following way: a smaller syringe was taped rigidly to the barrel of the 50-c.c. syringe (a small plastic wedge was placed between them to keep the barrels of the syringes parallel to each other), and a small piece of plastic was affixed to the stepping motor, so as to extend underneath the plunger of the second syringe, as well as the first—thus adapting the pump to drive both syringes. The smaller syringe was filled with hypertonic saline (or water, depending on the experimental condition) and was attached to the stomach fistula by way of polyethylene tubing. By means of this mechanism, each lap of the nozzle caused a small amount of water to be delivered to the rat's mouth, and, simultaneously, a proportionally smaller amount of hypertonic saline to be injected into the stomach. The ratio of these two amounts was precisely determined by the ratio of the internal diameters of the two syringes, since their plungers were moved through equal distances by the pump.

A preliminary experiment with this technique was carried out on 4 albino rats. One-hour drinking tests on each rat were conducted every other day for three weeks, with counter-injections into the stomach taking place in the first 30 min only. After each hour's test, water was left available to each rat for an additional hour in a different cage.

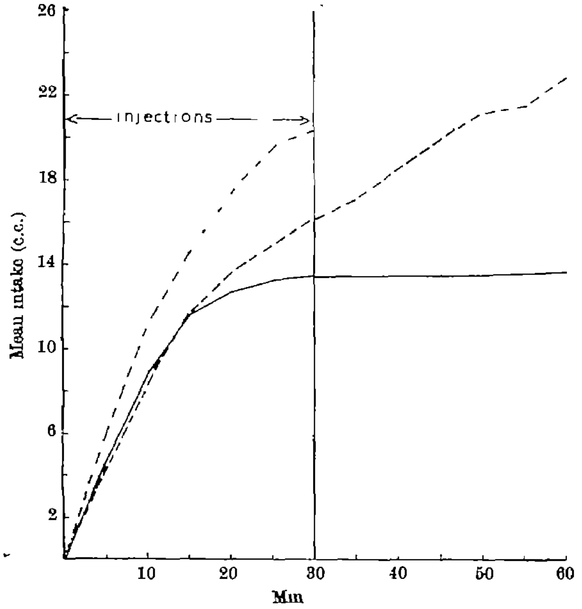

Fig. 1. ——, Water drunk, water injected, 0·1 : 1·0, ----, water drunk, 10 per cent saline injected, 0·1 : 1·0, —·—·—, 0·6 per cent saline drunk, no injection

Measurements of water ingested were taken at 5-min intervals during the test hour by reading directly from the scale on the 50 c.c. syringe, and the number of laps were obtained also from a counter, attached to the drinkometer. There were two experimental conditions: (1) the rats were allowed to drink water and counter-injections of hypertonic saline into the stomach rendered the concentration slightly above 0·9 per cent (operationally, for every c.c. of water drunk by the rat, 0·1 c.c. of 10 per cent saline was injected); (2) the rats were allowed to drink water and counter-injections of water (0·1 c.c. per c.c. drunk) were made into the stomach (control).

Cumulative drinking curves obtained from these tests show that the amount of drinking done in the first 15 min (when rats do most of their drinking following deprivation) is identical under both conditions, indicating that post-ingestional factors do not have an effect during this time. To test the possibility that these rates of drinking in the first quarter-hour might be the maximum possible for the rat, the same animals were allowed to drink 0·6 per cent saline in the same situation, though without injections. Under this condition, their rate of drinking was immediately greater than under previous conditions, and in 30 min they had ingested, on the average, more than they had in an hour under experimental condition (1). A replication of these preliminary tests is now being carried out, incorporating this third condition, in which hypotonic saline is drunk, while counter-injections render the solution of the same tonicity in the stomach as in the previous experiment.

Observations of the animals while drinking, with and without injections, showed that drinking patterns are not disrupted in any way by the technique; the rats seemed not to notice the injections at all, and very quickly adapted to the presence of the tubing connected to the fistulas behind their necks. Their general health was good.

This technique should prove applicable to a wide variety of experimental situations involving drinking behaviour in the rat.

This work reported was supported by U.S. Public Health Service grant *M*–4563 and National Science Foundation grant *G* 21376, while one of us (H. L. B.) was a Woodrow Wilson Fellow at Stanford.

A Significant Facet of Attention in Human Mental Activity

In the initial stages of observation, even with energy phenomena, instrumentation for measuring such a novel finding may not be available. At that time only the verbal formulation can be used to describe the event[1].

I have made numerous observations in the area of the parent–child (love) relationship or 'emotional-dependency-drive', or human-attention-seeking. About 15,000 cases were examined neuro-psychiatrically[2,3], which examination included in each case a review of historical data, the application of a variety of psychological tests, neuro-endocrine inspection, interview with parents and a psychiatric examination of the subject (juvenile). In addition, more than 1,000 cases of adults were diagnosed (examined) and were treated for neuro-psychiatric symptom-sign-complexes such as are found in a clinical neuro-psychiatric practice. Over the span of twenty years, tentative hypotheses[4,5] were formulated which now have been crystallized into a relatively comprehensive biological concept as will be expressed here in brief.

A dog is completely weaned (no attention needed) from its parent animal at 21 days. Weaning in infra-human animals indicates no further 'dependencies upon' or 'turning to' the parent animal. However, I have observed that if an alert and potentially aggressive species of dog, such as the German shepherd, after it has been weaned, is placed in a human environment, it becomes 'attached' mainly to one of the human objects. The dog actively turns-to or seeks-'attention'-from the human object-source, in competition with the attention-seeking-human-subjects of that same object-source. The dog demonstrates signs of jealousy and rivalry which may attain serious proportions even unto that which allegedly obtained between Cain and Abel. This observation regarding a special type of dependency or 'attention-seeking' probably classifies within the phenomenon of tropism (biological turning to)[6].

Implied in the foregoing sentences is a significant dimension which has not been formulated in the descriptions available in the literature[7,8] on the attention or in-attention components in the mental modality of the human nervous system.

Moreover, the fact that the dog's nervous system becomes involved in essentially a human neurophysiological event suggests that the semantic and symbolic phases of psychology are not required in the activation of this neural phase of attention-seeking or attention-response. Seemingly, in this essentially human dependency affair or motivation an effect is contaged[9] rather than communicated. Ostensibly, the fact that a dog becomes involved in this special area of functionality suggests that the evolutionary *anlage* for the process which becomes so magnified in the human is already established in the infrahuman animal.

The degree to which this phenomenon operates through fixed-action-systems (unconsciously) universally in the human being can only be determined by the extent to which each human being's behaviour reveals the human-attention-seeking-tendency. Psychosomatic symptom-signs (coronary spasm, vascular hypertension, gastro-intestinal ulcerations) which may become so intense as to cause death may also be part of the fixed action-driving-force operating in this entire complex, and suggests in part the violent intensity which Nature has invested in this attention-seeking-motivation.

In the human adult this element of attention-seeking appears to be a continuation of a process so evident in the human infant and child where the parental-attention or parental-type-of-love-effect is sought through: (*a*) extended crying[10] where no causative organic or physical disturbance can be found; (*b*) through excessive wakefulness where the parent continues to go back-and-forth to observe the infant; (*c*) later, through refusal to eat, especially where the parent pressures in that direction; (*d*) through temper tantrums; and (*e*) still later through positivistic (conforming) or negativistic (reactive) ('rebellious') behavioural patterns. As determinable from the legend, Did Cain kill Abel because of jealousy or rivalry for the limited attention available from Eve, their immature mother, who in turn through reactiveness was seeking a parental-type of love attention from her husband, Adam, as is evidenced by her' eating the apple when asked not to ?

Subserving the physiology in this essentially 'human-subject to human-object' tropistic phenomenon must be a real attribute of psycho-neuronal energy. Perhaps Freud's formulation of cathectic and super-cathectic energy[11] will be found related to a phase of the energy concept offered here. If such a relationship does exist then we have the beginning of a bridge between the Freudian psychoanalytic approach to mental therapy and the more recent biochemical (pharmaceutical) one as might be inferred from the succeeding paragraph.

As all physiology is subserved by biochemistry, ostensibly, this specialized psycho-neuronic physiology which the author is describing must be subserved by a specialized biochemistry. Is it then probable that the psycho-neuronic or emotional-dependency-motivation in the human is an evolutionarily acquired quality, or property of the human psychoneuronic apparatus, and that it is potentially adjustable through biochemicals[12,13] ? The answer to this question may be crucial to man's survival[14-16].

I am not describing a new natural principle; I am formulating a very important one, old as man, on a physiological, scientific basis. The human psycho-neural-dependency-appetite or motivant ('the need for parental love') proceeds as a type of mutual tropism (turning) between child and parent. A so-called rapport-tie, relationship, or bridge becomes established between them. This rapport-tie is a physical invisible bridge between human object and subject[5]. Relative to this theme, over the bridge, which is of variable strength, the parent, object, or donor transfers to the child that amount of psycho-neural-maturing-attribute ('love') it has available. The biopsycho-neural maturing process has qualitative, quantitative and temporal dimensions. The donor remains happy while supplying the maturing factor (psycho-neural attribute of energy) so long as the demand for it does not exceed the donor's available supply. The human infant, child, or subject is unwittingly, intensely driven by naturally established psycho-neural mechanisms to seek for the psycho-neural maturing factor from its attending objects or parental sources. The subject shows external and internal evidence of happiness, pleasure, or optimum biological functioning to the extent it actually obtains psycho-neural maturing factor through existing rapports. To the extent that a psycho-neural dependency need is unmet or to the extent that a psycho-neural functional maturation is incomplete, to that extent from birth to death does a subject, by various provocative or symptomatic ways, continue to seek further maturing effects and/or to seek relief from the stress of biopsycho neural functional immaturity. The biopsycho neural maturing factor is an attribute of energy developed in and by the (human) psycho-neural cortex[12,13].

Society of Chemical Industry (joint meeting of the London ection and Aslib Chemical Group, at 14 Belgrave Square, London, W.1), at 6.30 p.m.—Dr. G. M. Dyson. "Research at Chemical bstracts".

Wednesday, October 17

Institute of Navigation (at the Royal Geographical Society, Kensington Gore, London, S.W.7), at 4.30 p.m.—Annual General eeting. Dr. G. E. R. Deacon, F.R.S.· "Research and Navigation" residential Address).

Royal Meteorological Society (at 49 Cromwell Road, London, W.7), at 5 p.m.—Mr. D. H. Johnson "Rain in East Africa"; . P. Graystone: "The Introduction of Topographic and Frictional ffects in a Baroclinic Model".

British Nuclear Energy Society (at the Institution of Civil ngineers, 1–7 Great George Street, London, S.W.1), at 5.30 p.m.—. R. Hurst: "Dounreay Fast Reactor Operating Experience".

Institution of Electrical Engineers, Electronics Division Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. A. Ratcliffe, R.S.. Chairman's Address.

British Institution of Radio Engineers, Computer Group the London School of Hygiene and Tropical Medicine, Keppel reet, Gower Street, London, W.C.1), at 6 p.m.—Discussion on: tandard Logical Elements".

Oil and Colour Chemists' Association, London Section (at Royal Society of Tropical Medicine and Hygiene, Manson House, Portland Place, London, W.1), at 7 p.m.—Dr. S. Cotson: "Education and Training for the Surface Coatings Industry".

Royal Institute of Chemistry, London Section (joint meeting th the British Society for the History of Science, at the Science useum, South Kensington, London, S.W.7), at 7 p.m.—Dr. A. ow "The Chemical Industry before Muspratt".

Thursday, October 18

University College, London (in the Anatomy Theatre, Gower eet, London. W.C.1), at 1 15 p.m.—Prof. P. E. Corbett "The d and the Ladder—Pets, Beasts and Monsters in Greek Art".*

Society of Chemical Industry, Road and Building Materials oup (at 14 Belgrave Square, London, S.W.1), at 2.30 p.m.—Meeting "Problems in Sampling Road and Building Materials".

nstitution of Mining and Metallurgy (at the Geological iety, Burlington House, Piccadilly, London, W.1), at 5 p.m.—neral Meeting.

innean Society of London (at Burlington House, Piccadilly, don, W.1), at 5 p.m.—Dr. P. B. Tomlinson: "The Vegetation of Florida Everglades"; Prof. C. F. A. Pantin, F.R.S.: "A Relict ine Fauna".

niversity of London (at the London School of Hygiene and pical Medicine, Keppel Street, Gower Street, London, W.C.1), .30 p.m.—Prof. D. A. K. Black· "The Alimentary Tract and y-Fluid".* (Second of eighteen lectures on "The Scientific Basis Medicine" organized by the British Postgraduate Medical Federa-".

oyal Society of Tropical Medicine and Hygiene (at Manson se, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. A. J. gan. "A Survey of Sleeping Sickness in Northern Nigeria, from Earliest Times to the Present Day" followed by a Discussion. rman· Sir George McRobert.

Thursday, October 18—Wednesday, October 24

World Congress of Underwater Activities (at Church House Westminster, London, S.W.1).

Friday, October 19

British Society for Parasitology (in the Meeting Room of the Zoological Society of London, Regent's Park, London, N.W.1), at 10.30 a.m.—Meeting on "The Application of New Techniques to Parasitology". Chairman· Sir John Randall, F.R.S.

Photobiology Group (at the Institute of Ophthalmology, Judd Street, London, W.C.1), at 2.30 p.m.—Meeting on "Physiology and and Photochemistry of the Eye".

University of London (at Imperial College of Science and Technology, Prince Consort Road, London, S.W.7), at 5 30 p.m.—Prof. H. Mohr (University of Freiburg): "The Control of Plant Growth and Development by Visible Radiation".* (Further lectures on October 22 and 23.

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. S. F. Singer (Washington). "A Satellite's View of the Weather".

Saturday, October 20

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. W. K. Ford. "Tropical Insect Life".*

Monday, October 22

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5 30 p.m.—Discussion on "Earthing Arrangements for Electrical Equipment, with particular reference to Double Insulation".

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, W.C.2), at 5 30 p.m.—Dr F. G. Heath: "The Theory and Practical Value of Ternary Systems".

Royal Geographical Society (at 1 Kensington Gore London, S.W.7), at 8.30 p.m.—Mr. Brian J. Moser and Mr. Donald Taylor: "Lost Tribes of the Piraparana".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned.

Lecturer (with a special interest in teaching and research in applied mechanics) in the Department of Mechanical Engineering—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (October 18).

Lecturer (competent in physiological psychology and/or experimental psychology) in Psychology—The Registrar, The University, Leicester (October 20).

Lecturer (with a good honours degree or equivalent) in Chemistry, to teach all branches to G.C.E. (A), and Physical Chemistry and/or Organic Chemistry to degree and Grad.R.I.C. level—The Principal (HE.4/C/2806/10), L.C.C. Norwood Technical College, Knight's Hill, London, S.E.26 (October 20).

Chair of Mathematics—The Registrar, University of York, The King's Manor, York (October 22).

Chief or Senior Technician in the Department of Zoology—The Secretary to Council, Westfield College (University of London), Hampstead, London, N.W.3 (October 22).

Experimental Officer or Senior Experimental Officer in the Department of Mechanics, for duties which will include the design and construction of electronic and optical apparatus for studying turbulence, aerodynamic noise, and flows at very high speeds including their interaction with magnetic fields—The Registrar, The University, Manchester 13 (October 24).

Lecturer or Assistant in Clinical Chemistry in the Department of Pathology, Queen's College, Dundee, and the Royal Infirmary, Dundee—The Secretary, University of St. Andrews, Queen's College, Dundee (October 27).

Assistant Experimental Officer (with a sound knowledge of genetics and chemistry, and a degree in either of these subjects) in the Department of Applied Genetics—The Secretary, John Innes Institute, Bayfordbury, Hertford, Herts (October 31).

Lecturer or Assistant Lecturer (preferably with a special interest in biogeography or surveying) in the Department of Geography, University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 31).

Statistician (with a first- or second-class honours degree in mathematics, with statistics) with the Agricultural Research Council Statistics Group, School of Agriculture, for the application of statistics to agricultural research, and computer programming—The Secretary, School of Agriculture, Cambridge (October 31).

Director (honours graduate, preferably in mathematics, with postgraduate training, and previous experience in a computing laboratory), to take charge of the newly instituted Computer Unit which is to be developed within the university over the next few years—The Secretary, The University, Edinburgh (November 1).

Lecturer or Senior Lecturer in Zoology at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1, (Australia and London, November 1).

Lecturer or Assistant Lecturer in Agricultural Biochemistry, Mathematics, and Physics (two vacancies) at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 8).

Professor of Inorganic Chemistry—The Registrar, University Registry, Oxford (November 8).

ASSISTANT LECTURER IN PHYSICAL CHEMISTRY—The Secretary Queen's University, Belfast, Northern Ireland (November 10).

GRADUATE PROGRAMMER IN THE COMPUTATION LABORATORY, for duties which will include advising users in programming and operating a Ferranti Pegasus computer to which magnetic tape is to be added—The Secretary and Registrar, The University, Southampton (November 10).

LECTURER OF ASSISTANT LECTURER IN THE DEPARTMENT OF SOCIAL ANTHROPOLOGY—The Secretary, The University, Edinburgh (November 14).

LECTURER (Grade II) IN PHILOSOPHY—The Registrar, The University, Bristol 8 (November 15).

LECTURER or ASSISTANT LECTURER IN PHARMACOLOGY at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 15).

PROFESSOR OF PATHOLOGY—The Registrar, University Registry, Oxford (November 15).

ASSISTANT (preferably with a degree in horticulture or botany) AT THE ROSEWARNE EXPERIMENTAL HORTICULTURE STATION, Camborne, Cornwall, for research on time of heading and quality in winter cauliflower—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

PHYSICIST, PHYSIOLOGIST or PHYSICAL CHEMIST, to assist in research on pulmonary function—Dr. M. L. Thomson, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1.

POST-DOCTORAL RESEARCH ASSISTANT (graduate, preferably with research experience in X-ray crystallography), to investigate the structure of liquids and solutions by X-ray diffraction methods—Dr. R. Mason, Department of Chemistry, Imperial College of Science and Technology, London, S.W.7.

READER (with appropriate research experience) IN PHYSICS—The Registrar, Department 26/I, Bradford Institute of Technology, Bradford 7.

UNIVERSITY FREEDOM AND THE ACADEMIC DEFENSIVE

THE firmness and dignity with which the free universities of South Africa opposed the policy of the South African Government towards the universities, culminating in the Separate University Education Act of 1959, won the respect and admiration of the entire academic world, as was manifested at a notable meeting in London in November 1957. It was at a general assembly of the University on April 16, 1959, when the Bill was in its final stages in the South African Parliament, that the University of the Witwatersrand, after affirming the principle that a university is a place where men and women without regard to race and colour are welcome to join in the acquisition and advancement of knowledge, pledged itself to continue faithfully to defend this ideal against all who have sought by legislative enactment to curtail the autonomy of the University. Accordingly, the assembly dedicated itself to the maintenance of this ideal and to the restoration of the autonomy of the University.

To commemorate in every third year this occasion, the University established a Chancellor's Lecture, the first of which was delivered on April 4, 1962, by Sir Eric Ashby. Entitled *Universities under Siege*, this lecture has now been published by the University*. In thought and language it is a heartening and inspiring paper. Without commenting on the policies of the South African Government which are so widely regretted, Sir Eric sets forth not merely the argument for the free university but also the nature of its responsibilities in a world when in all universities so many of the values they cherish are endangered. Taking, as it were, the torch from one passage in the essay, "The Open Universities of South Africa", in which five years ago, at the height of the controversy, the university set forth with clarity and dignity its function in the Union of South Africa, Sir Eric illumines that ideal, expounds its relevance in this changing world and points to the opportunities as well as the problems which confront us in applying it fully in our times.

"Experience shows that a society, however successful it may have been in the past, will not long survive if it cannot cope with the tasks of a new era. For this reason every civilized society tends to develop institutions which will enable it to acquire, digest and advance knowledge relevant to the tasks which, it is thought, will confront it in the future. Of these institutions, the university is the most important."

From that text Sir Eric expounds the uniqueness of universities among social institutions, emphasizing first the dual loyalty which springs from their universality. Because they deal with concepts which command the assent of educated men irrespective of race, colour, religion, language or politics, they cannot fully serve the society which maintains them unless that society grants them certain privileges so that they can also be loyal to the international brotherhood of universities. They are within the State, yet they must preserve an individuality apart from the State. They cannot exist except in the matrix of politics, yet they must remain out of the reach of politics.

The university's claim to these privileges which are not granted to other institutions in society can be based on tradition, precedent and statute, often of centuries standing, but Sir Eric wisely does not rely solely on this legalistic approach alone. Precedents and traditions are not immutable: indeed, Dr. Emil Brunner remarked in his Gifford Lectures that in a world in which democracy, in the sense of equality, has become a kind of religion, tradition can neither be kept nor be formed. This, he continued, is one of the main causes of the instability of Western society during the past two centuries, and although the Union of South Africa is notably conservative and traditional in outlook, it is somewhat paradoxical that so sharp a threat to the university ideal should have emerged there. However, even in Britain it is obvious that the climate of opinion is increasingly bringing under examination such institutions as the University Grants Committee and that the new universities are likely to need all the help which they can receive from such co-operative institutions in their developing and formative years.

Sir Eric Ashby fully recognizes that precedents and traditions are for ever being eroded by research and reflexion on social problems and that the history of academic freedom records many setbacks. These setbacks, however, have strengthened, not destroyed, the concept of a university, and from this he argues that the defence of academic privilege is best based on the empirical observation that without its privileges a university cannot fully serve the society which maintains it. Academic privilege is not just a tradition: it is a necessity.

In developing his argument here, Sir Eric is arguing fundamentally for the free society, for, although it is above all in the university that new ideas are nurtured and tested, controversy develops, and out of controversy deeper understanding, the process is not confined to the university. The university is the principal instrument of society for adventurous and constructive thinking, the forum for dialectic over intellectual affairs, and no outside prejudice or interest should be allowed to hinder the adventure of thinking, the clash of minds, the search for truth. Sir Eric Ashby said frankly that a nation where thinking is rationed cannot survive in the world of to-day, and he pointed out that university privileges are preserved in all intellectually healthy countries, even though the universities in these countries have long since lost their defences against the State. In Holland, Western Germany, France, and the British Commonwealth, in the United States (apart from a few private universities) the universities now depend on the State for finance. In none of these countries is there any effective formal defence against invasion of their traditional privileges, and yet in all their privileges to select students and staff, to plan courses and curricula, are respected and honoured.

---

* Universities under Siege. (The Chancellor's Lecture.) By Sir Eric Ashby. Pp. 19. (Johannesburg: University of the Witwatersrand, 1962.)

These privileges, Sir Eric Ashby argues, are thus retained not by power but by popular consent, because it is recognized that the privileges have been shown to be necessary. The possessions which matter most in a university are not buildings, not even its library and equipment, but its ideas, and quality of ideas depends on quality of staff. First-rate staff will not work under conditions fixed by those who are afraid of ideas. Moreover, it is probably true to say that the widespread concern with which the disagreement between the Government and the University Grants Committee over university finance was viewed in Britain this spring was due to the fear not so much that university expansion would be checked as that the universities would be unable to attract and retain sufficient staff of high quality.

Turning then to discuss the duty of a university, Sir Eric addresses some heartening words to the open universities of South Africa. Referring with deep understanding to their present difficulties, he points out that those universities have not betrayed their privileges from within, and that the way in which the University of the Witwatersrand is resisting the challenge from without commands the admiration of the academic world. Such is an inspiration not merely to older institutions in Cambridge and Harvard, Berlin and Leyden, but also to the much younger institutions in Dakar and Ibadan, Khartoum and Salisbury, and, not least, the two at present under siege in Ghana. Some of the universities in tropical Africa have, in fact, particular reason to be grateful to the University of the Witwatersrand for its declaration of April 16 because their integrity too is threatened by racial discrimination. The stand which Nigerian intellectuals are taking to keep their universities truly cosmopolitan, to prevent them from being mere staff colleges for African nationalists, would have been much more difficult, Sir Eric states, if the open universities of South Africa had succumbed without protest to the legislation of 1957.

Universities, he continues, are all members of a supra-national community and serve their local communities by supplying an international commodity—scholarship, science, technology, medicine—on international standards. They cannot fulfil even their national purposes unless they are loyal to cosmopolitan traditions of what universities represented. If a few of the great universities were to compromise on level of attainment among students and level of scholarship among staff the integrity of all universities would be endangered, and that is equally true of compromise over privileges and immunities. That is why the stand which the University of the Witwatersrand is making against the violation of one of its privileges is a defence not only of itself but also of universities everywhere. A university which is unfaithful to its own traditions in order to appease the State or to gain temporary advantage debases the currency of its scholarship and betrays its own academic staff.

Lastly, Sir Eric Ashby looks to the tasks of the future. Turning back to the passage in his text, "a society will not long survive if it cannot cope with the tasks of a new era", he reminds us that universities have become key instruments in a continual adjustment of society to its environment, and this is nowhere more evident than in Africa. A university must be responsive to its environment, but in responding it must not break faith with the supra-national brotherhood of universities and the traditions it inherits from them. To strike the balance, over standards and privileges, he reiterates, the university must be firmly uncompromising; over the currents of thought which run through it and the pattern of government it adopts, the university must be relevant to its own society.

Probably no part of Sir Eric's lecture was more stimulating to his audience than the following passage in which he sought to interpret what this meant in terms of the curricula and statutes and regulations of a South African university. Its relevance for the universities of the British Commonwealth generally is no less apparent, whether in what he had to say about problems of self-government in modern universities or about the problem of responsiveness to currents of thought. It is not simply that he extends the spectrum of subjects of study. His comment on the social mimicry of European education in the universities of tropical Africa, especially in the faculties of arts and social studies, is not for those universities alone. It has deep implications for the universities of Great Britain and should be pondered by the Commonwealth Educational Conference as well as by the Department of Technical Co-operation and those bodies, like the Nuffield Foundation, which have been seeking to foster the study of the questions to which he refers and on which the fate of the African continent may well depend.

If questions like the transfer of ideas from Ibo to English, the impact on the African mind of European ideas of justice and equity, how systems of social welfare replace the obligations of the extended family, or what tensions occur in the African when he becomes urbanized and has to discipline himself to a routine and work either with Europeans or like Europeans are to be rigorously and impartially examined, an immense amount of help must be forthcoming. Some of it is already being organized from the United States, but here is a responsibility which should be accepted primarily by Britain and towards which the Commonwealth universities and the Overseas Research Council could and should be making a significant contribution.

Sir Eric Ashby primarily challenges the University of the Witwatersrand and other universities in multiracial communities with their unique opportunities to study this hurricane of culture-change and to ensure that every student is persuaded to think systematically about the problem as a basic ingredient of his or her higher education. It is essentially a problem in the humanities, and as these universities respond to the challenge, new ideas are likely to result from which the great dilemma of South Africa itself may be solved. But just as it must mean much to a university under siege to know that its refusal to compromise on standards and privileges earns it the respect and support of universities generally, so its attempt to observe in scholarly manner, to understand, and perhaps in a small way to influence the course of Westernization in Africa, it should be sustained by the knowledge that those problems are also thought worthy of study by the universities of the Commonwealth, and that the universities of the United Kingdom in particular are engaging strenuously in that task. Admirable projects have indeed already been undertaken by some universities in Great Britain, but much more generous support could well be forthcoming to the young universities of Africa through the Overseas Research Council in the critical study of the greatest human problem of our age: the peaceful co-existence of people of different races. Universities generally may be grateful for Sir Eric's noble words; the University of the Witwatersrand will the sooner be able freely to bring the black and white peoples of South Africa together in that adventure of scholarship in the measure in which Britain herself discharges her own responsibilities in that same field.

Since the lecture was delivered the Sabotage Act has become law and the area in which resistance is effective has been further narrowed. Something of how much those defending freedom generally in South Africa appreciate the support of the outside world may be sensed from the statement Chief Lutuli, Nobel Peace Prizewinner for 1960, wrote before the Act became law. Publication of that message has been prohibited in South Africa, and it would be premature to deduce from the publication of the Chancellor's lecture that there has yet been any weakening in the Union Government's assault on civil liberties generally or any pause in its tragic pursuit of apartheid. Sir Eric remarks trenchantly that the only convincing evidence for apartheid existing in a university would be the inferiority intellectually of black men to white.

EVOLUTION: BIOLOGICAL AND HUMAN

Evolution and Man's Progress

Edited by Hudson Hoagland and Ralph W. Burhoe. Pp. 181. (New York and London: Columbia University Press, 1962.) 4.50 dollars; 36*s*.

THIS unusual and stimulating book includes contributions from two dozen men eminent in genetics, palæontology, evolution, systematics, general biology, social and cultural anthropology, psychiatry, psychology and sociology. It is clearly impossible to review it in detail: all I can do is set down some of the reflexions to which it has given rise.

In the first place, it is a symptom of the present crisis in 'man's progress'. Neither the physicochemical sciences and their application in technology, nor the traditional ideas of the political or economic 'sciences', nor the pseudoscientific ideologies like Marxism, turn out to provide a satisfactory basis for human thought and action in regard to progress. Accordingly, thinking men are turning towards the biological and the human sciences in an attempt to reach some new and more satisfying synthesis.

This book is a welcome contribution to this effort. However, it does not go far enough in the direction of what one of the contributors terms 'synthesism', but which I would prefer to call simply integration. So far as I can see, the new synthesis must grow out of the concept of evolution as an operative process. We need to have in mind not merely the genetic basis of evolution, whether biological or human, not merely the results of small-scale evolution of populations or species, but the process as a whole, with special reference to how it produces its extraordinary results, like highly complex animal organization, mind (behaviour accompanied by subjective awareness), human societies, and science itself.

This means considering human evolution as a continuation of biological evolution, but operating with the aid of quite new (psychosocial or sociocultural) mechanisms, and producing quite novel kinds of result. Until very recently the social anthropologists and psychologists and sociologists have fought shy of thinking in evolutionary terms. So far as I know, the Darwin Centennial at Chicago in 1959 was the first occasion when a number of them were prevailed on to join with their biological colleagues in doing so. In 1960, Sahlins's and Service's symposium on *Evolution and Culture* continued the process. And the paper by Steward and Shimkin in the present volume takes an important further step in this direction. They write, "our treatment of culture and its evolution rests upon nine heuristic concepts which constitute a mixture of hypothetical postulates and real but tentative observations". This is already half-way to the method used by Darwin in regard to biological evolution. What seems to me missing is a central concept, something analogous to Darwin's principle of natural selection, which provided the directive agency in the biological process.

Doubtless we shall in due course be able to formulate the principles of 'psychosocial selection'*. Meanwhile, a biologist may suggest that one essential step towards a general theory of evolution in its psychosocial phase should be to consider actual societies and cultures, existing and historical, from a functional–evolutionary point of view—how do they work, and how did they, their genetic bases, and their psychosocial organs, like science, religion or art, originate historically?

This will bring out the cybernetic character of all evolutionary processes, the share of feedback in their mode of operation. This is becoming increasingly recognized (for example, by Waddington) in biological processes, both ontogenetic and phylogenetic. The recognition of its importance in cultural evolution will invalidate not only all semi-mystical theories, like Spengler's or Toynbee's, but also all those involving a rigid predeterminism, like Marxism.

---

* Since writing this, I find that Hoagland himself (*Clark Alumni Univ. Mag.*, No. 264; 1962), following H. A. Murray, has stressed that "ideas may be considered to social evolution what genes are to biological evolution", and that therefore "social environmental selectivity"—in other words, psychosocial selection—operates between competing ideas. See also my introduction to *The Humanist Frame* (Allen and Unwin, 1961)

This sort of approach would make it impossible for social scientists like Prof. Skinner (p. 133) to consider "governmental, religious, economic, educational and therapeutic institutions . . . simply as behavioural technology" aimed at "the control of human behaviour", and to treat their evolution as "part of the history of technology".

Nor, if a truly integrative approach and method is adopted, will it be possible for so many sociologists, psychologists, and even biologists to continue the ostrich-like reductionism which manages to avoid looking the facts of mind and its evolution in the face by sticking its head into the arid sands of behaviourist materialism. 'Mind' and 'matter', the subjective and the objective, are in fact integrated in actual evolving organisms, and the mental or subjective component eventually becomes dominant in man. If I may coin a new term, we need an integrative *eductionism*, which studies processes with reference to their outcome and results instead of only analytically with reference to their origins and component elements.

The next main task of the biological and social sciences will be to study this integration and all its operative implications. Prof. Maslow (p. 162) rightly says that this involves a new philosophy of science, which envisages understanding as its goal rather than control, and relies on intuition and empathy as well as on logical analysis and controlled experiment. In this connexion, it is good to find that distinguished evolutionist, G. G. Simpson, writing (p. 109) "as a man's mind is more than the sum of neuron minds, so the collective mind of mankind is clearly a very different thing from man's individual mind". This 'collective mind' is what Teilhard de Chardin rather loosely called the "nöosphere"; a better term might be 'nöosystem'. We would then find that different grades of cultural evolution were characterized by differently organized nöosystems.

In the biological section of the book, Prof. Muller's plea for an effective eugenic programme is a vivid reminder of the need for man to think seriously about his future destiny before it is too late.

Prof. Crow has made a valuable contribution to human evolutionary genetics. But he continues to use the unfortunate terminology of the population geneticists, who define 'fitness' "in a strictly Darwinian [*sic*] sense", in terms of differential reproductive success. This, I feel sure, is bedevilling the whole Darwinian theory, of evolution by natural selection. I would prophesy that within the next few years evolutionists would distinguish sharply between two kinds of selection, which may be called survivance selection and reproductive selection, the former operating through the differential survival of individual organisms, the latter through their differential fertility. Biological evolution operates mainly by survivance selection. Reproductive selection only comes into play as a major factor in exceptional cases like that of display in polygamous-promiscuous birds. Darwin must have been aware of the distinction between the two types of selection when he set up sexual selection as something essentially different from natural selection.

In man, survivance selection, though operating strongly in early stages of human evolution, is now largely in abeyance. But in man (as R. A. Fisher stressed 32 years ago in his classic *Genetical Theory of Natural Selection*), owing to his unique variability in effective fertility, reproductive selection is playing an increasingly important, and on the whole unfortunate, part. During biological evolution, the survivance type of selection operated to produce a steady improvement of organisms, both singly and collectively. The resultant general trend is not merely one towards adaptation in the usual limited sense, but deserves the title of advance or progress, and can be objectively defined in such terms as more efficient exploitation of environment, greater self-regulation and independence of environmental changes, fuller awareness, more flexible behaviour and greater capacity for profiting from experience.

Improvement and advance are always relative to what Darwin called the conditions of life; these include not only the particular environment of single species, but the global conditions of life as a whole.

A study of evolutionary improvement, both large-scale and long-term as well as small-scale and short-term, would seem to be a necessary prerequisite for a fully fruitful discussion of the subject of this book, *Evolution and Man's Progress*. For example, such a study would make it impossible to discuss eugenics in terms of some supposedly "ideal population" (p. 59): the only tenable ideal for eugenics is one of continuing improvement of the human stock, by raising the level of a number of desirable genetic qualities. It would also make it possible for sociologists and human psychologists to think in truly scientific and adequately comprehensive terms about human evolution, whether cultural or genetic, in the psychosocial phase. Let us hope that Profs. Hoagland and Burhoe will organize a second symposium and discussion on "Man's Improvement". Meanwhile, we are grateful for the valuable results of this first meeting of minds on the subject. JULIAN HUXLEY

TRANSMISSION IN CLOSED WAVEGUIDES

Electromagnetic Waveguides and Cavities

By Prof. Dr. Georg Goubau, in collaboration with Prof. Dr. Richard Honerjäger and Prof. Dr. Rolf Müller. (Physics and Technology, Vol. 5.) Pp. xvii+656. (London and New York: Pergamon Press, 1961.) 100*s*. net.

THIS book is a translation of a work by Prof. Goubau and his former colleagues in the University of Jena, first published in 1955. It covers the work they carried out at Jena prior to 1945, but was not published until 1955 due to difficult post-war conditions. Most of the manuscript was written between 1945 and 1947, but some changes were made at a later date. However, as the work is largely theoretical, the delay between the original work and its present publication in translation does not detract from its merit.

The book deals with the theory of transmission in closed waveguides, of fields in cavities, and coupling to cavities and the theory of networks of elements connected by waveguides. Surface waves and the type of surface waveguide associated with Prof. Goubau's name are not dealt with in this book.

It is unfortunate that while the text has been translated the mathematical symbols have not been changed from the original Gothic type, which is not readily recognized by most English readers, especially when not clearly reproduced. In the text some of the Gothic symbols have been set in Roman type, while others have been left in the original type, which is confusing on a first reading. The figures, also, have not been clearly reproduced.

The book will be of interest to those familiar with basic waveguide theory and concerned with the more advanced aspects of the theory. Throughout the book the general mathematics of the different problems are considered first and then the application of the theory to more practical situations. The book may also be of interest for comparing the separate development of this type of problem in Germany and in Great Britain and the United States during the war years.

The translation of foreign works into English is to be encouraged so that developments abroad are readily accessible to English-speaking readers. It would be unfortunate if the deficiencies in mechanical processes used should lead to a more limited use of these translations than might otherwise occur.

P. A. MATTHEWS

SAFETY IN NUCLEAR ENGINEERING

Technology, Engineering and Safety

Edited by C. M. Nicholls. Vol. 3: Pp. viii + 448 + xii. 105*s*. net. Vol. 4: Pp. viii + 523. 140*s*. net. (Progress in Nuclear Energy Series, Series 4.) (London and New York: Pergamon Press, 1960 and 1961.)

IN reviewing the two latest volumes in the series edited by C. M. Nicholls and comparing the contents with those of Volume 2, published in 1960, one is struck by the considerable reduction in the number of reactor types which are discussed. Thus, the later volumes concentrate predominantly on gas- and water-cooled systems and there is only occasional mention of other coolants. This trend is not unexpected or, indeed, unwelcome, since the large majority of power reactors being developed or constructed are either gas-cooled ('*Magnox*', '*A.G.R.*', '*H.T.R.*') or water-cooled ('*P.W.R.*', '*B.W.R.*' and variants).

Volume 3 is divided into four chapters under the headings of engineering, technology, nuclear safety–criticality and nuclear safety–reactor safety. The 15 articles comprising these chapters are all written by experts in their respective fields and generally reach a high standard. An article on steam as a reactor coolant is of particular interest at the present time. It forms a valuable introduction to the subject and highlights some of the problems to be overcome before successful superheating reactors can be commercially exploited. Rather more than half the book is devoted to various aspects of safety and there are five articles on criticality, some of which make fascinating, if sobering, reading.

Volume 4, the latest in the series, follows the same general layout as its predecessors. There is a chapter under the heading process technology, containing four articles reporting American experience on the gas–solid and liquid–liquid chemical engineering operations involved in uranium processing and the reprocessing of nuclear fuels. Other noteworthy contributions include reviews on various aspects of high-temperature gas-cooled reactor technology. This subject is particularly appropriate at a time when widespread attention is being given to the ultimate development of the gas-cooled reactor, from Calder Hall on one hand, to the *Dragon* Project at Winfrith in Dorset and similar high-temperature reactor projects in the United States and Germany, on the other. Water-cooled reactor technology is covered by an article on the important subject of boiling stability and by an informed discussion on recent developments in zirconium alloy corrosion. There is also an article in the reactor safety section on recent developments in the study of metal–water reactions. This is still an open subject, but the present review goes a long way towards clarifying the issues involved.

The chief criticism of this series is that it attempts to cover too wide a range of subjects; for example, the various aspects of safety could well be the basis of a separate series. With this reservation, the present books constitute a valuable fund of information, well presented and indexed, which should be of special interest to those already having some experience in this field. Some of the articles contain a wealth of references (one in Volume 4 has 241 and another 136) which the reader will find of considerable assistance in following up subjects in which he has a particular interest.

INFORMATION THEORY

Information Theory

Papers read at a Symposium on Information Theory held at the Royal Institution, London, August 29th to September 2nd, 1960. Edited by Colin Cherry. Pp. xi + 476. (London: Butterworth and Co. (Publishers), Ltd., 1961.) 95*s*.

THIS volume contains the thirty-six papers and discussion presented at the fourth London Symposium on Information Theory. The expositions extend beyond pure information theory and are classified under the headings of: coding and detection theory and statistical theory; telecommunication systems; human reaction to information; sensory information and biological models; learning mechanisms and other artefacts; classification theory, syntactics and semantics. The papers were presented by active research workers, and the subjects range from mathematics (for example, the ten papers under the first two headings) to experimental psychology (such as most of the eleven papers under the third and fourth headings).

A general comment on the content of the symposium may be of interest. The former, fairly well defined, boundaries of such traditional subjects as applied mathematics, psychology, physiology and information handling (documentation, bibliography and general library procedures) are rapidly being swept away, and concepts and methods of one discipline are making deep inroads into neighbouring territory. This process is nowhere illustrated better than in the present volume on information theory. The successful research workers in this field will, in future, find it necessary to be able to speak with the psychologist, physiologist and librarian on his own territory, and this will particularly apply to the applied mathematician who sets out to contribute to one or more aspects of the subject. This, it is clear, is likely to have a profound effect on the structure and content of undergraduate courses in the universities. It will not be enough for the applied mathematician to learn only about the applicable parts of pure mathematics and their use in physics and engineering; nor will the psychologist and physiologist be able to forego, somewhere in his upbringing, an introduction to the ideas of probability, statistics, classification theory (in a mathematical sense, such as expounded in the papers by Golomb and by Rescigno and Maccacaro), and the experimental techniques of the physical sciences. For the librarian, interested in the development of new methods for information handling (storage, retrieval, classification and so on) rather than in the operation of an existing system, the position is even more difficult. He will need a training embracing a much wider field than that covered in the existing courses in librarianship.

It is evident that we are in the middle of a scientific revolution, concerned not so much with content in the various fields but with the very strong interactions which are developing between these fields. This, it is safe to forecast, will mean that the next few decades will produce scientists having a very different orientation from those of recent decades. To anyone concerned with these developments the papers of the fourth Symposium may be recommended as indicating in a vivid way some of the problems which will have to be faced in drawing up the new structure. L. S. GODDARD

VEGETATION OF THE SCOTTISH MOUNTAINS

Plant Communities of the Scottish Highlands

A study of Scottish Mountain, Moorland and Forest Vegetation. By Dr. Donald N. McVean and Dr. Derek A. Ratcliffe. (Monographs of the Nature Conservancy, No. 1). Pp. xiii+445+26 plates. Over 60 Tables. (London: H.M. Stationery Office, 1962.) 77*s*. 6*d*. net.

THIS is the first of the monographs to be produced by the Nature Conservancy, and its aim is to describe and classify the vegetation of the Scottish mountains. Previous works, limited to regional studies of Highland vegetation, have been made by ecologists since 1900 onwards, but the aim of the authors is to extend the surveyed areas and provide a wider outlook. It does not claim, however, to be complete, and large areas have still to be surveyed. The authors were faced with the problem of arrangement, whether to base the contents of the monograph on an ecological or a systematic system or on the life-forms of the dominant species. They have chosen rightly the third method of approach as the main basis for classification. It is similar in effect to one based on altitudinal zonation. A standard treatment is adopted for each community or type of the vegetation and full analysis of the floristic composition of each is given in sixty tables. The geographical distribution, habitats, relationship to other communities, and very full information about soils and other environmental features are provided in the tables. There are also very useful distribution maps of the various types of communities and large folding maps of the present distribution of the oak, pine and birchwoods and their distribution during this climatic period.

The methods of collecting and arranging data are more or less those used by Poore and Dahl. It became clear to the authors as the investigation proceeded that the various types of vegetation found on the Scottish mountains form a continuous series, that there may in places be sharp discontinuities between types, but that in wider areas a complete series of intermediates can usually be found. It was therefore necessary to make a selection of a sufficient number of points in this continuous series as reference units which would adequately give an idea of the whole range. The term *nodum*, coined by Poore for reference points in a continuous series, is therefore used, and the names of associations and noda have been based on the names of their most prominent or dominant constituents. Tables 1 and 2 give a list of noda with their characteristic constants and dominants.

After the introduction and description of methods used in the survey follow chapters dealing with the vegetation from the forest up through the dwarf shrub heath, grass heath, herb and fern meadows to the moss heaths of the higher altitudes. There are chapters on bogs, mires, springs and flushes.

A comparison is made with Scandinavian vegetation, and close similarities are evident between the Scottish noda and their equivalents in Norway. The authors conclude that Scottish mountain vegetation must be regarded as an oceanic extension of that of north-west Europe. The similarity in climate and flora results in the same altitudinal zonation and appearance of the vegetation in Scotland and Norway. The differences that exist must be due to greater exposure to Atlantic gales, higher summer and winter temperatures and more extensive grazing by farm animals in Scotland. There is a very strong similarity between the plant communities round springs and in flushes where there is little or no grazing and where the controlling factor, wetness of soil, is largely independent of climate and altitude. The effects of climate on the vegetation, particularly those due to snow cover and solifluction, are carefully considered.

More than half the book consists of tables, including sixty-four lists of species occurring in the selected noda, and the geographical distribution of these noda in the localities surveyed. There are also thirty-four vegetation distribution maps and numerous tables to indicate the distribution of vegetation and soil types in the principal areas. There are twenty-six photographs illustrating some of the characteristic facies of the vegetation, a usefu bibliography and excellent idex.

The Conservancy and the authors are to be congratulated on producing a book, well written and excellently illustrated, which gives not only a wealth of useful information, but also will undoubtedly stimulate further research on Scottish vegetation It will be of value not only to ecologists, who will be able in the future to detect changes if they occur in the vegetation as the result of succession or change of climate, but also to those interested in the preservation of Nature or who are concerned with the utilization of Scotland's natural resources. Since 195 the investigations have been in progress, and the authors have covered a wide area of the Highland in all weathers and made profuse notes in the field from which these printed records are compiled Nothing like this has been hitherto accomplished in the British Isles. It approaches the type of survey for which the ecologists and plant geographers o Montpellier and Toulouse are well known, and should be made available to all libraries and botanica departments.

The planning and printing of the book and quality of the tables, maps and illustrations, leave little t be desired. JOHN WALTON

STUDYING THE EVER-CHANGING SEA

By Sir ALISTER HARDY, F.R.S.

The following is an abbreviated version of only part of the Evening Discourse given at the British Association meeting at Manchester on September 8. Its title there was "Man and the Beneficent Sea". I am here using a different heading which is more appropriate for the piece I have selected for publication in *Nature*: that mainly describing some new and recent work of the Edinburgh Oceanographic Laboratory. The first section of my lecture dealt in general terms with the natural economy of the sea and my conviction that man will have to get more from it in the future to feed his increasing populations. After emphasizing the differences between the basic plant production on the land and in the sea, and its effect on animal life, I referred to the possible future use in the sea of various methods akin to farming; these I had previously discussed at a symposium in Section D (Zoology) of the Association's meeting at Cardiff two years ago when they were also reported in *Nature* (188, 91, 1960). The entire lecture will be published in *The Advancement of Science*.

THERE will no doubt be many new ways in which we shall be able to increase the harvest of the sea when we come to have a greater knowledge of it. The scientists of the different Government laboratories in Europe have already built up an enormous body of information about the lives of our fish and their environment: a knowledge won from the sea under great difficulties. Linked with their work is that of the independent laboratories such as those of Plymouth and Millport, and the National Institute of Oceanography in Great Britain, where research work into the more fundamental background conditions are undertaken. While all these laboratories have done wonders with the resources available, the resources are not enough. The ocean is vast: it is a hidden world, and its exploration is expensive. Compared with what we are spending on physical, or on agricultural research, we are not yet, I believe, putting an adequate proportion of our available revenue into the work which will, if sufficiently supported, yield so much more of the sea's beneficence for the future of mankind.

I have just mentioned the difficulty of the ocean being a hidden world; there is another great difference between the sea and the land that I particularly want to emphasize: the fact that it is always on the move. The sea is a dynamic system; it is useless to think of it as we think of the terrestrial world. While the sea-bed is fixed, the planktonic pastures which nourish its life are for ever changing; conditions in one year may be very different from those of last year or the year before that. If these changes affect the life of the sea-bed, as surely they must, still more will they influence fish like the herring which feed directly on the plankton; moreover, all the bottom-living fish spend a vital part of their young lives up in the plankton which may be favourable for them in one generation but not in the next.

For many years now I have been urging the need for studying the changes in the ocean in the same sort of way as we study those of the atmosphere. A great deal of my time before the War was spent, when a professor at Hull, in developing a method of recording planktonic changes over wide areas. I shall describe here some of the results now coming from the work I started just thirty years ago; they are those obtained by the splendid band of enthusiasts who have carried on the work since I left off. They have now extended the survey of monthly observations right across the Atlantic to America and northwards to the Arctic Circle. It is their achievement, and not mine, that I want to discuss; I should, however, briefly sketch its beginnings.

The continuous plankton recorder, on which this survey is based, has frequently been described; I need only indicate its nature. Somewhat torpedo-shaped and fitted with diving planes, it will swim below the surface at a constant depth when towed behind a ship; as it goes along it continually samples and preserves the plankton on a long gauze banding wound on to a spool by a propeller turned by its passage through the water. For every mile of sea traversed a small section of the gauze winds on; at the end of a run, of perhaps 400 miles, the spool is taken out, unwound below a microscope and the plankton estimated. The first machine was used on the 1925–27 *Discovery* Expedition to the Antarctic; on my return from this voyage and appointment to Hull, I modified it for use on commercial ships crossing the North Sea. With the kind co-operation of a number of shipping lines we first ran from Hull to a number of Continental ports and so covered the southern North Sea with a network of lines of observation; monthly charts of the main changes in the plankton began to emerge. In 1937 H.M. Treasury, on the advice of the Development Commission, increased its support to enable us to open another laboratory at Edinburgh to run similar lines from Leith to cover the northern part of the North Sea; we also began a line into the Atlantic towards Iceland.

The North Sea is affected by an influx of oceanic water which rounds the north of Scotland to pass down the east coast of Britain and by a lesser flow up the English Channel through the Straits of Dover; the force of these may vary considerably. The spread of certain plankton organisms characteristic of these waters can be used to indicate their relative strength and extent. From our monthly charts we could see areas of plant and animal plankton change their positions, wax and wane with the passage of time; as the years came to be compared we could see striking differences between them. An examination of the changing plankton is indeed very like charting the weather; we are studying moving centres, not of high and low pressure, but of high and low plankton production, and of many different kinds. As in meteorology we can only understand these changes by having many observations made over a wide area at the same time, and repeated at intervals; fortunately the waters move much more slowly than the atmospheric disturbances.

The War brought a temporary halt to the activities; but when peace came, the team came together again, first under Dr. C. E. Lucas, who had been with me from the beginning; I had now become Linacre professor at Oxford. Dr. Lucas then became director of the Scottish Fishery Laboratory at Aberdeen and was followed by Dr. K. M. Rae until he took a professorship in the United States in 1957; now Mr. Roland Glover is in charge of the enterprise. The Edinburgh Laboratory, much enlarged as the Oceanographic Laboratory under the ægis of the Scottish Marine Biological Association, has now

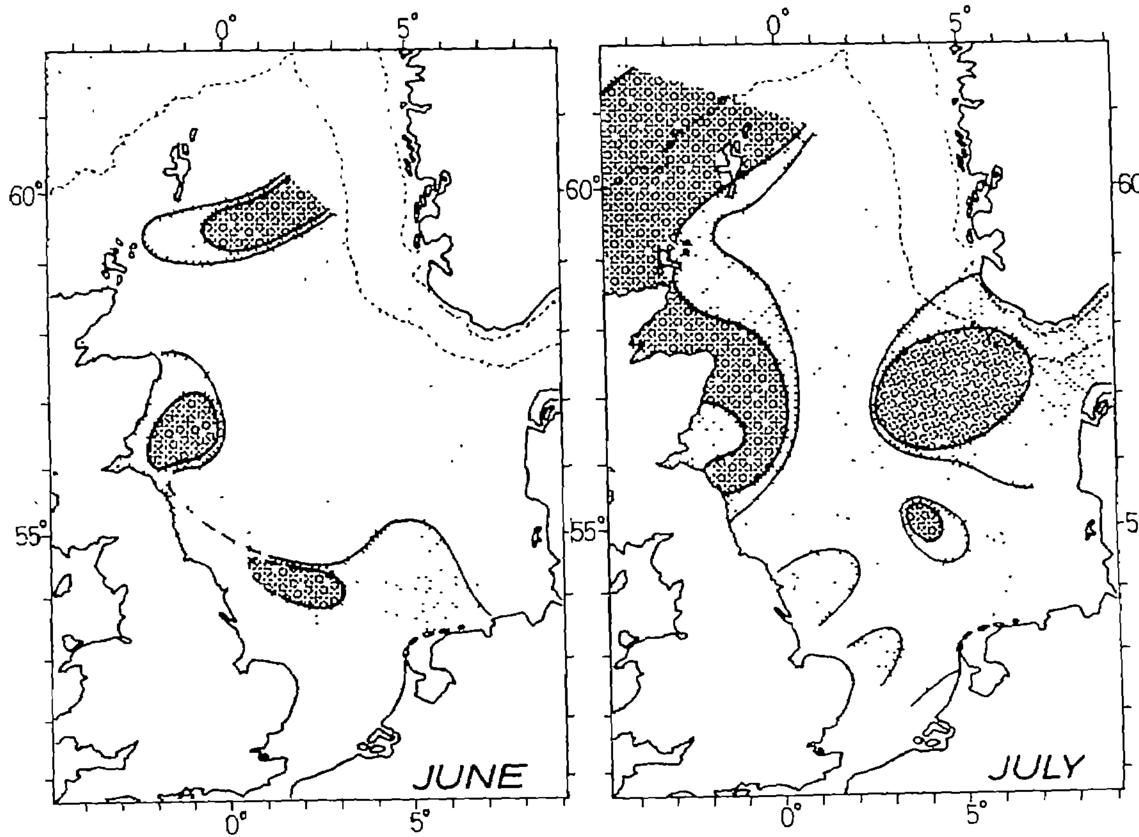

Fig. 1. Charts showing how the distribution of the total phytoplankton in the North Sea has diverged from a 18-year average during June and July 1961. The heaviest and lightest shadings represent, respectively, values of more than 150 and less than 50 per cent of the norm for the month

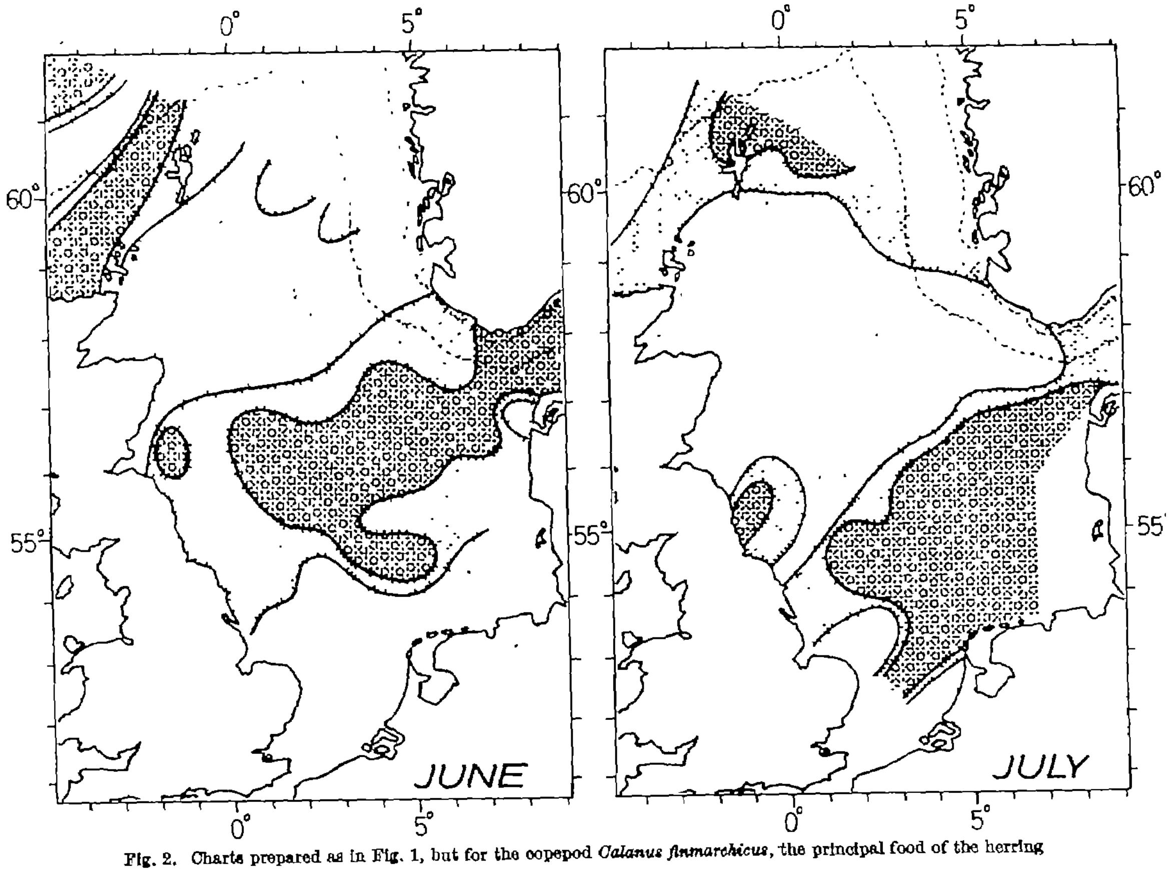

Fig. 2. Charts prepared as in Fig. 1, but for the copepod *Calanus finmarchicus*, the principal food of the herring

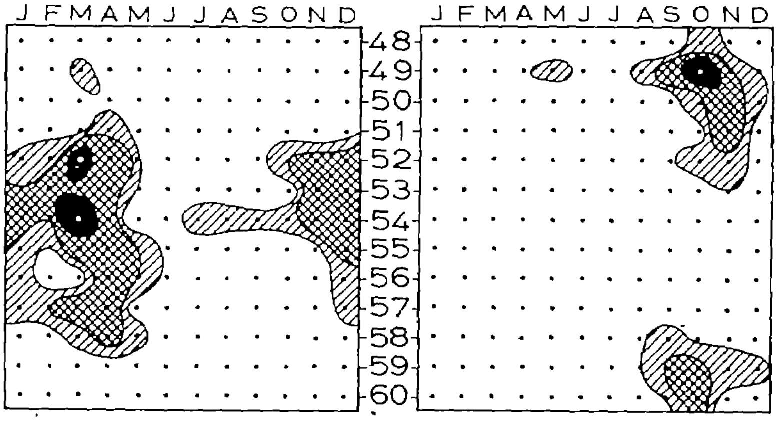
become the headquarters of the survey. It is some of the work of these leaders who followed me, and of their staff, that I want to present.



Thalassiothrix longissima

Corycaeus anglicus

Fig. 3. Diagrams showing the varying degrees of abundance of two plankton organisms, the diatom *Thalassiothrix longissima* and the copepod *Corycaeus anglicus*, in the North Sea over the months and years of 1948–60

After the War the work gained the valuable addition of lines into the Atlantic and to the north run by Norwegian, Dutch and British weather ships on their way out to and from their stations. This greatly increased the significance of the work, for it had long been recognized that the conditions in the North Sea must to a large extent be determined by still earlier events in the western ocean, that is, farther back in the track of the North Atlantic current before it rounds the north of Scotland. Quite recently the Edinburgh Laboratory published[1] its first *Atlas* of this area showing the distribution of no less than 80 of the more important plankton species based on the average of all the month's results for the past ten years. The charts represent the 'normal' distribution for the organisms concerned; they form a basis to which patterns in different years may be compared to see how at any one time the particular organism may have departed from its 'norm'. As the work proceeds and the 'norm' becomes based on a longer series of years, it will increase in reliability; the period is now fourteen years.

The charts in Figs. 1 and 2 show, as examples, such divergences demonstrated in the North Sea for the total phytoplankton and the copepod *Calanus*, the most important food of the herring, for June and July of last year (1961). They are prepared in the following way. The North Sea is divided into a grid of squares, and for each important organism a set of 13 such grids is made, one for each month of the year; each is then filled in to show, square by square, the 12-year average quantity of the organism in question for the particular month concerned. Thus month by month we can see how far the occurrence of each organism is diverging from its norm; the values are now filled in in the squares on a chart for each month as percentages of the norms, and so maps of such deviations can be produced. In the examples shown the contour lines are drawn at levels of 75 and 150 per cent of the normal; the heaviest shading represents quantities over 150 per cent, the medium shading those between 75 and 150 per cent (that is, near the normal) and the lightest shading indicates values below 75 per cent.

The teams at the Edinburgh Laboratory have over the years given us many interesting correlations of events in the plankton; they are now providing the material for quite a new understanding of the sea. Their long and patient work is now being rewarded with a splendid achievement. They now have the means of showing how any one area in any one month departs from the long-term mean; the charts reproduced are just one example of how such data can be used. It is the first time these have been published. I think I am not exaggerating when I say that I feel their gaining the ability to do this marks a really important break-through in the means of investigating this changing hidden world. They are now beginning to have their hands on the pulse of the sea, the flowing changing streams of the plankton which are the link between the inorganic world and the fortunes of the fisheries. A much longer time, of course, must elapse before the mean is based on a sufficient number of years to enable one to think of predicting the effect of such changes on a fishery; but progress in that direction is well under way. By the use of computers, the Edinburgh oceanographers are now treating a large number of different species to give us an idea of how the whole plankton community is changing with its environment.

They can also express the yearly differences in plankton occurrence in a number of ways. Fig. 3 gives an example of one such method; here we see diagrams showing the relative abundance of two organisms in a large area of the North Sea ranging over the months from left to right (January–December) in each year as we pass down the diagram from top to bottom (1948–60). Each value used represents the average for the whole area for the month concerned; contours of the changing values with time are then drawn. As experience grows we shall learn more of what these patterns mean in relation to changing hydrology on one hand and fluctuations in the fisheries on the other.

Now a further phase of expansion is just beginning. In recent years, since 1959, they have pushed farther westward with an experimental line from Iceland to Newfoundland on a ship sailing between Reykjavik and New York. This has shown a much richer plankton in the area to the south of Greenland than had been expected and the presence of a great many of the young of the fish *Sebastes marinus* (the red fish or Norway haddock), which indicates the presence of a great stock of this species waiting to be fished as soon as a satisfactory method of mid-water trawling can be devised. The results from this line have created much interest in North America where the authorities have encouraged an extension of the survey in the western Atlantic, particularly in relation to their fisheries in what is known as the 'ICNAF' area (International Commission for the North-west Atlantic Fisheries). The Edinburgh Laboratory has been awarded a contract by the U.S. Office of Naval Research which, together with increased financial support from the British Treasury, will permit the establishment of a trial survey linking the European and American continents. Last year (July 1961) the first new route was started with this international

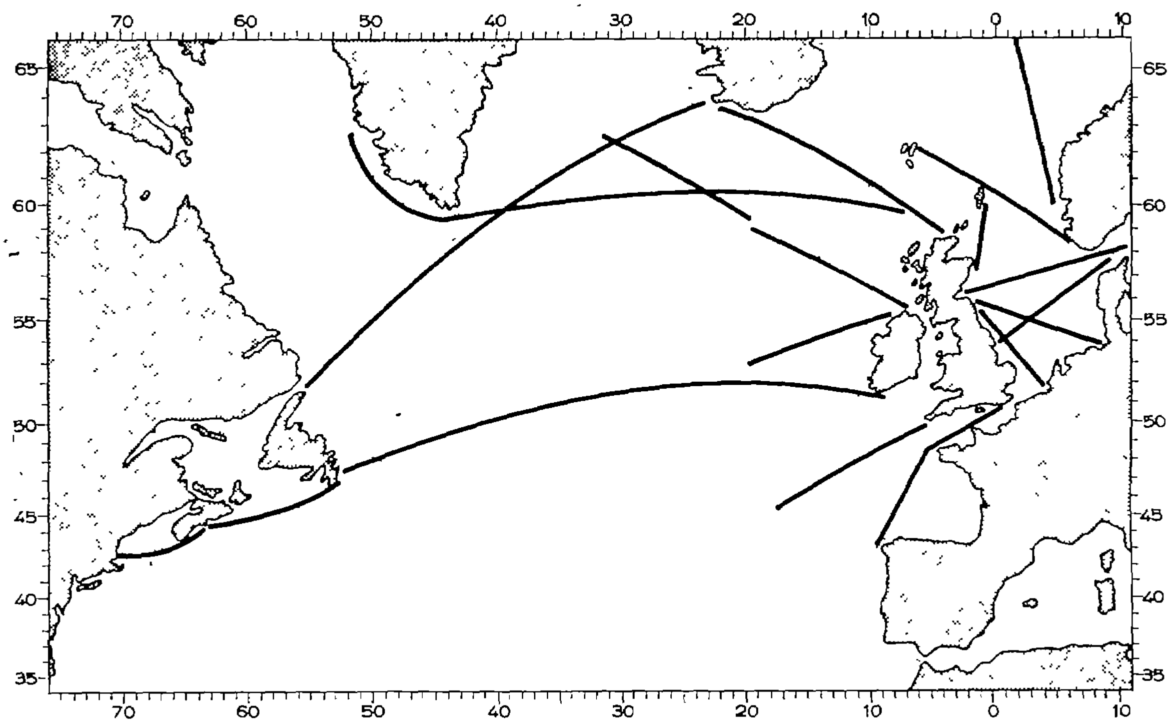


Fig. 4. A map of the monthly plankton recorder routes covered by the Edinburgh Oceanographic Laboratory in its survey during 1962

support; it runs across the ocean between Liverpool and Newfoundland and then down the continental shelf to Halifax (Nova Scotia) and Boston (Massachusetts). In Boston, American scientists kindly help to service the gear aboard the ship. Another new route was started early this year (1962) with the help of the Royal Greenland Department of Trade; this is sampling between Scotland and Greenland. The latest map of the survey is shown in Fig. 4. All the recorder samples from this wide survey are being returned to the Edinburgh Laboratory, where the staff is being augmented by additional members, some of whom are coming from the United States to get training in the methods which have been standard practice in Edinburgh since the survey was resumed after the War. I would like to stress the international nature of this work; there are 25 ships equipped to tow recorders from Denmark, the Faeroes, Germany, Holland, Iceland, Norway and Great Britain.

It is just thirty years since the present type of recorder was designed. It has only been improved in minor details because any major changes would have destroyed the basis of standardized sampling over a long period. However, there is a limitation to the method which we believe can be overcome in a new machine. The recorder on the survey is run at one standard depth: 10 metres below the surface. The need for sampling over a range of depth is accentuated by the fact that a number of plankton animals carry out a diurnal vertical migration; on this account the distribution of some species can only be considered from records taken at night, and for others the method is at present inapplicable. It is hoped in the future to modify the recorder so that it describes an undulating path as it is towed, rising and falling in every mile to cover the vertical range of the more important species; the technical difficulties, however, have not yet been fully solved, although we feel confident that they will be in time. Nevertheless, in spite of this limitation, it is clear, I think, from the results obtained that a survey run at a single depth can yield significant results. Over many years the average number of fish-eggs taken by the recorders in the southern North Sea give a graph which corresponds closely with that for the average yearly landings of trawl-caught fish in the same area; the two curves rise and fall together. It is, of course, what we should expect—more fish, more eggs—fewer fish, fewer eggs; yet to see the correlation come out of the survey gives confidence in its reliability. Again there has been a remarkable correspondence in the North Sea between the average quantities of the copepod *Calanus*, the principal food of the herring, and the annual variations in the growth of the three-year-old herring coming into the shoals as reported by the Lowestoft Fisheries Laboratory.

The object, in my lecture, was to discuss how we might make more of the beneficence of the sea than we are at present doing. Earlier (as explained in the introductory remarks) I had instanced a few ways in which we might be able to increase the yield of the fisheries; they would only be the small beginnings of a far greater use of these resources which must come when we have a fuller knowledge of this hidden part of the world. I have tried to show how we can only hope to gain a proper knowledge of it if we recognize that it is a constantly moving world and treat it as such. The biologists and the physical oceanographers are now ready to come together to give us one dynamic picture of its month-by-month changes. Only when this is done and the environment is studied as a changing physico-biological whole will man fully inherit the Earth by understanding its better half.

A MOLECULAR MODEL FOR BIOLOGICAL CONTRACTILITY: IMPLICATIONS IN CHROMOSOME STRUCTURE AND FUNCTION

By DR. ARTHUR COLE

Physics Department, University of Texas, M.D. Anderson Hospital and Tumor Institute, Texas Medical Center, Houston 25

JACOBSON[1] has suggested that the quasi-crystalline state of water may be a major factor in the 'structuring' of macromolecules. A helical molecule fits ideally into the water lattice if pitch-lengths and diameters are multiples of the water lattice dimension of 4·75 Å. The displacement of the water in the lattice exposes polar water groups which can bind to polar groups of the macromolecule and, therefore, stabilize the helix. Jacobson suggested that these principles seem to apply to the structure of the (double) helical deoxyribonucleic acid (DNA) molecule. Diffraction data[2,3] give a pitch-length of 33·6 Å for DNA, which is about equal to seven water-cell layers (33·2 Å). The pitch-length of 28·1 Å for DNA in the dehydrated *A* form is about equal to six water layers (28·4 Å). The diameter of 19·5 Å and the packing distance of 18·8 Å for parallel aligned molecules in less than 60 per cent relative humidity corresponds to about four water layers (19·0 Å). At 92 per cent relative humidity, the packing distance increases to about 23·5 Å (which corresponds to the incorporation of one water layer between molecules), while at higher humidities the molecules tend to dissolve out (separate) into the water.

Jacobson's[1] suggestion provides a basis for a possible contractile mechanism. If a hydrated molecular helix associates co-linearly with a fibrous molecule by ionic bonding, charged groups along the associated side will be neutralized and binding to water weakened. If one or more water layers per helical turn is lost from the affected side, a secondary coiling (Fig. 1) will result. The outer diameter, *D*, of the secondary coil will be:

$$D = \frac{2d}{1 - \frac{L - 4{\cdot}75\,n}{L}} \qquad (1)$$

where d is the diameter, L is the pitch-length of the primary helix, and n is the average number of water layers per turn displaced from the neutralized side (dimensions in Å).

This secondary coiling, which represents a distortion or change of the initial state, would be stabilized by the ionic binding energies and the fit of the larger helix into the water lattice structure. Further associations may be inhibited because of the necessity of bending the fibrous molecule to conform to the secondary coil configuration before extensive coupling can be achieved. Water bound between turns of the secondary coil would tend to set the pitch-length.

Advanced (tertiary or quaternary) coiling might be formed by successive associations with larger protein fibres. The formation and dissolution of such secondary and advanced coilings would be sensitive to agents such as monovalent and polyvalent ions, dehydrating agents, heat, etc., which affect both the associability and the water binding of molecules. Small ionic changes could lead to coiling ⇄ uncoiling transitions, if an initial concentration were close to a critical (equilibrium) value.

Co-linear associations also might be formed if an initial coupling between a relatively small monomer and a helical structure is followed by a linear polymerization of the small units along one side of the helix. Polymerization along the other side of the primary helix must be inhibited if the association is to lead to differential dehydration and advanced coiling.

The formation of a secondary coil can result in two kinds of contractile movement, depending on strand-length. Association of relatively short strands would produce a bending motion, while association of long strands would result in a large linear contraction of ten-fold to twenty-fold resulting from the multiple coiling (Fig. 2).

Implications in Chromosome Structure and Function

The helical structure of DNA[4] and the coiled mitotic chromosome[5] are generally recognized. Many suggestions for intermediate chromosome structure have been made; for example, the branched structure suggested by Taylor[6], the multi-stranded structure by Steffensen[7] and Kaufman and De[8], the side-chain structure by Schwartz[9,10], and the coiled coil structure of Inoué and Sato[11]. A structure presented here is based on a successive series of helical condensations of a linear thread composed of DNA segments covalently joined by short segments of either protein

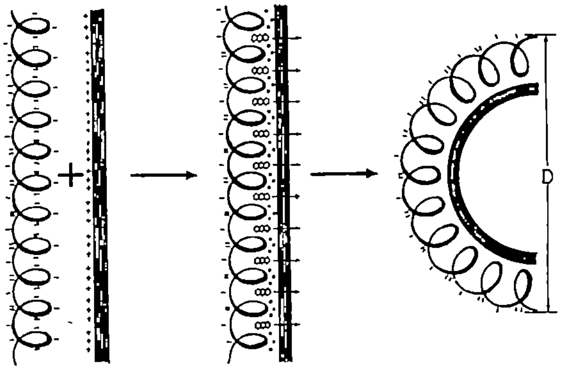

Fig. 1. Association of a hydrated helical molecule with a fibrous molecule. One-sided neutralization leads to a differential loss of water and secondary coiling

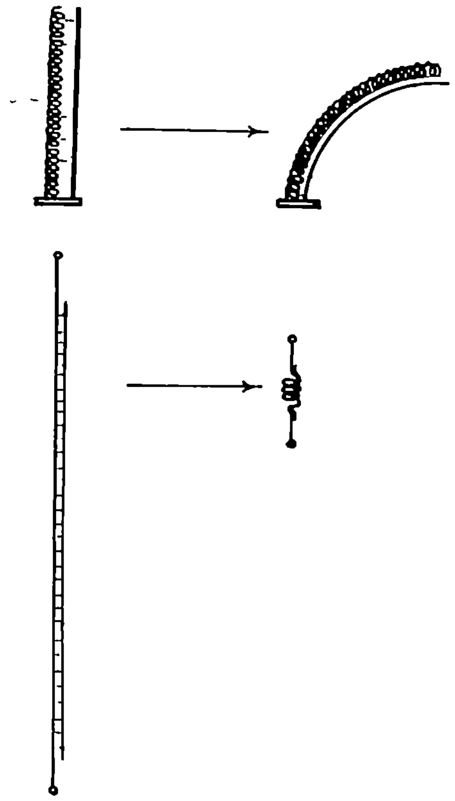

Fig. 2. Association of short strands leads to bending (top) Association of long strands produces large linear contractions because of multiple coiling

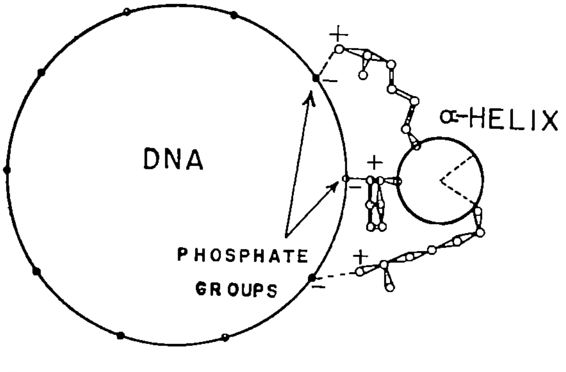

Fig. 3. Possible co-linear relationship between DNA and an α-helix. Arginine residues of the histone can couple to adjacent phosphate groups

or specialized DNA. The coilings are assumed to result from associations of DNA with histone protein.

Histones. Protein extracted from chromosomes by high ionic strength solutions generally consist of 2 or 3 (or 6) fractions[12-14]. For example, Phillips and Johns[13] show that a first, very small fraction is eluted from a carboxymethylcellulose column with 0·005 N hydrochloric acid; a second large fraction (containing about 2/3 of the protein), eluted by 0·01 N hydrochloric acid, is rich in lysine; and a third fraction, eluted by 0·02 N hydrochloric acid, is rich in arginine.

The histone mass is somewhat greater than or equal to the DNA mass[14] and probably couples to the DNA by ionic linkages to the phosphate groups[15]. The α-helix occurs in the protein of natural nucleoprotein[16] and synthetic nucleoprotein[17]. Stereochemical relations between histone and DNA have not been determined, although various co-helical relationships have been proposed[3,15,18,19].

It seems unlikely that the different histone fractions perform the same function, since they are of unequal amount and have different amino-acid contents, end groups, and elution (or associability) characteristics. It is suggested here that the arginine-rich fraction (defined here as histone *A*), equal to about 1/3 the DNA mass, is most closely coupled to DNA, and that the lysine rich fraction (defined as histone *B*) equal to about 2/3 the DNA mass, is less closely associated, while another fraction (histone *C*) is weakly associated.

Helical condensations. A co-linear relationship between an α-helical protein and DNA involves no initial distortion of the structures and provides for the coupling of basic protein residues to about 30 per cent of the DNA phosphate groups (Fig. 3). The protein mass corresponds to 31 per cent of the DNA mass. This association would produce a secondary coiling of 138 Å diameter (which also 'fits' into 29·0 water-layer units) if two water layers were differentially displaced from the DNA helix.

From work on the side-packing of DNA[2,3] it is likely that such a secondary coil could incorporate one or several water layers between turns because of the intermediate phosphate neutralization existing in this region. If a larger fibrous protein, histone *B*, were then to associate co-linearly with the secondary helix (fibril), and lead to the loss of one interturn water layer from the associated side, a 1400 Å diameter tertiary helix (chromanema) would result (Fig. 4A).

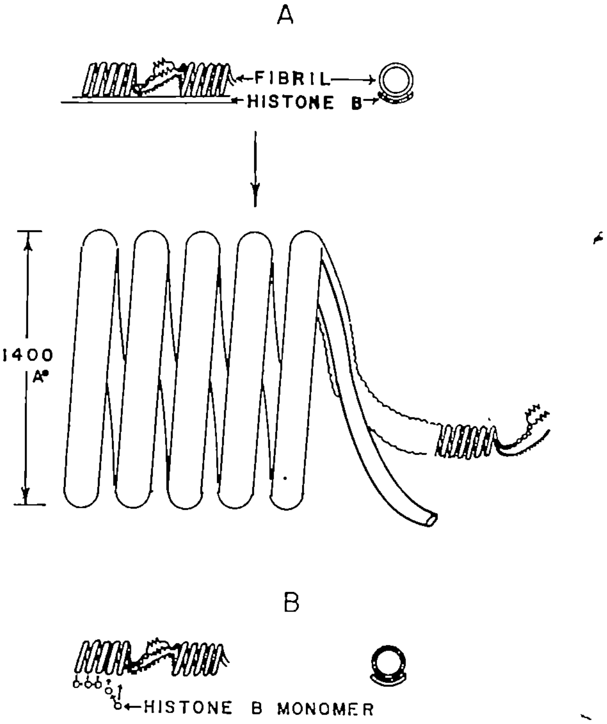

Fig. 4. A, associations of a DNA fibril with histone *B*, leading to a tertiary coiling (chromanema of 1400 Å diameter; B, alternative scheme for co-linear coupling, between a fibril and histone by means of a linear polymerization of histone monomers (40,000 mol. wt.) along one side of coil

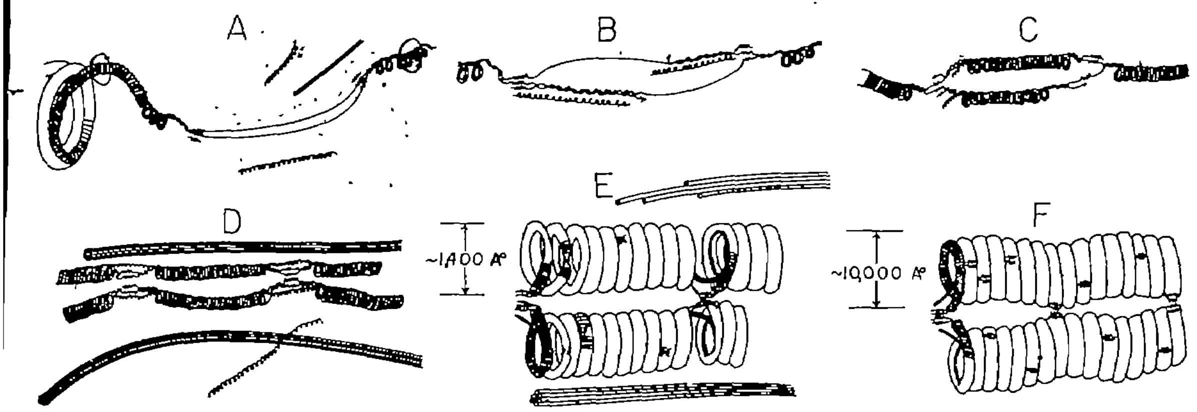

Fig 5. DNA replication scheme. Uncoiled segment (A) is replicated in opposite directions (B), and associates with histone *A* and coils into two fibrils (C) Adjacent segments are replicated (D). Association with histone *B* leads to chromanema (E). During mitosis, sister chromanema associate with histone *C* and condense into sister chromatids (F) (reduced scale)

It is estimated that in such a configuration, only about 15 per cent of the phosphate groups could be neutralized by a lysine-rich histone with a weight per length comparable with the fibril. Thus, the coupling of histone *B* would be considerably weaker than that of histone *A*.

An alternative possibility is that co-linear relationships are formed by a linear polymerization of histone monomers along one side of a helix. A histone monomer of 40,000 molecular weight[13] corresponds in size to a 20 × 200 Å rod (or a 50 Å sphere), which would conveniently fit along the fibril and equal about 50 per cent of the DNA mass (Fig. 4B).

The number of water layers bound between turns of the chromanema may be high because of the many charged phosphate groups in this region. If one interturn water layer is differentially removed following a co-linear association of histone *C* with the chromanema, the quaternary coil (chromatid) would be about 8μ in diameter. A more reasonable chromatid dimension of 1μ would require a differential removal of 11 water layers per turn. Histone *C* could form only weak associations with DNA because of the relatively smaller number of ionic bonds available when coupling large structures, and would exist as nucleoprotein only in the mitotic chromosome.

Although ambiguities arise in interpreting electron micrographs of chromosome structure, helical structures of the dimensions predicted for the secondary and tertiary coilings have been reported, and appear to be present in electron micrographs by Ris[5,20], Moses[21], Mirsky and Osawa[22], Kaufman and De[8], Yasuzumi and Ishida[23] and others.

Approximately 0·1 × 10^{-12} g of DNA is contained in a mammalian mitotic chromosome about 1μ × 5μ in size. A chromosome of this size formed by the suggested primary through quaternary coilings would contain 0·133 × 10^{-12} g of DNA and is, therefore, comparably condensed.

Replication. DNA replication probably involves an opening of the double helix into the two strands which then act as templates for the synthesis of new complementary strands[24]. Synthesis probably occurs linearly in one polarity along each DNA strand. Since complementary DNA strands have opposite polarity, synthesis must progress in opposite directions along complementary strands.

DNA synthesis occurs in interphase and lasts an appreciable fraction of the growth-cycle, that is, 7–10 h in mammalian cells[25,26]. Work on radiation-induced chromosome damage[27,28] indicates that two 'sub-units' of the chromosome tend to separate at the beginning of the DNA synthesis period. It may be that during the DNA synthesis period, a local change in ionic concentration in the region of the chromosome leads to a DNA dissociation with histone *B*, a weaker association with histone *A*, and a weakening of the base pair hydrogen bonding in the DNA molecule.

A general replication scheme is outlined in Fig. 5. Synthesis is initiated at specialized (link) regions of an uncoiled intermediate segment (Fig. 5A), and proceeds in opposite directions along the two strands (Fig. 5B). The new DNA associates with histone *A* and coils into two fibrils (Fig. 5C). Adjacent segments are similarly replicated (Fig. 5D) and then associate with histone *B* and coil into a chromanemal winding (Fig. 5E). During mitosis, the sister chromanema associate with histone *C* and condense into sister chromatids (Fig. 5F).

It is assumed that the short links (possibly protein), unlike helical DNA, do not form advanced coilings and maintain loose (ionic) attachments between sister chromosomes throughout the entire replication process. Although many points of attachment may be broken during the condensation sequence some attachments will remain. Thus, the model provides for chromosomal homology at every biological level, from the level of DNA complementary pairing to that of the mitotic chromosome.

Replication requires unwinding the DNA helix and, therefore, rotation of the chromosome. It is estimated that the relational rotation-rate of a mammalian chromosome replicating in this way would be about 100 turns per sec. Similar estimates for diverse materials such as *T*2 phage, *Escherichia coli* cells, yeast cells, and *Paramecia* yield a comparable rotation-rate; that all these materials synthesize DNA at a rate in the order of 10^{-14} g/h/chromosome.

This large mechanical activity represents a substantial objection to the model. It is known, however, that nuclei of living cells are engaged in much random motion. The stirring action could enhance the distribution of substrates.

This work was supported in part by the U.S. Atomic Energy Commission contract *AT*–(40–1)–2832.

Many of these ideas arose from conversations with Dr. Carolyn Somers, Mrs. Ruthann Langley, and Dr. William C. Dewey. I also thank Drs. Ronald M.

CHEMISTRY OF MUSCLE CONTRACTION

ADENOSINE TRIPHOSPHATE AND PHOSPHORYLCREATINE AS ENERGY SUPPLIES FOR SINGLE CONTRACTIONS OF WORKING MUSCLE

By DR. D. F. CAIN, A. A. INFANTE* and PROF. R. E. DAVIES

Departments of Animal Biology and Molecular Biology, School of Veterinary Medicine,
University of Pennsylvania, Philadelphia

CONTRACTING muscle is one of the most fascinating 'machines' in Nature, but, despite an enormous effort, it has so far not been possible to find the immediate source of energy which allows this mechano-chemical system to turn chemical free energy into external work. Following the work of Fletcher and Hopkins[1] in 1907, Parnas and Wagner[2] in 1914, Meyerhof[3] in 1920, it was generally accepted that the energy for muscle contraction came from the breakdown of glycogen to lactic acid. However, in 1930, Lundsgaard[4] showed that iodoacetate-treated muscles could contract many times without producing lactic acid. During these contractions, phosphorylcreatine (PCr) was found to break down and thus appeared to be the source of energy. Lohmann[5], in 1934, found that the co-factor for the breakdown of PCr in dialysed cell-free muscle extracts was adenosine diphosphate (ADP). Thus, it was generally accepted that the dephosphorylation of adenosine triphosphate (ATP) to produce ADP and inorganic phosphate was the initial reaction for the provision of energy for contraction in spite of the fact that the content of ATP remained unchanged except in extreme fatigue. This view was supported by experiments with isolated enzymes, muscle protein solutions, fibrils made from reconstituted actomyosin, and glycerinated muscle models which strongly suggest that ATP is in fact the immediate source of energy for muscle contraction[6].

However, in 1954, Fleckenstein, Janke, Davies and Krebs[7] published experiments showing that frog rectus abdominis muscles could contract and do work at 0° C without measurable net change of energetically equivalent quantities of ATP, ADP or PCr (that is, about 0·5 µmole/g at 50 per cent efficiency), while Mommaerts[8] reached similar conclusions on the basis of experiments with turtle leg muscles at 0° C in which measurements were made of ADP, adenosine monophosphate (AMP), creatine, creatinine and pyruvate during contraction and relaxation. Since then, many other phosphorus compounds have been tested and found not to undergo sufficient net changes during contraction. These include carnosine di- and mono-phosphates[9], all the inosine, guanosine and cytosine phosphates, phosphoenolpyruvate, all the phosphoglyceric acids[9,10] the phosphorus in the total acid-insoluble residue of muscle measured either as inorganic phosphate, phosphatido-peptide phosphorus, phospholipid phosphorus, ribonucleic or deoxyribonucleic acids[11]. Other relevant experiments[12] have been reviewed by Davies and Cain[13].

Since we had found that inorganic phosphate was certainly liberated during a single muscle contraction (Table 1), and no other compound could be observed to account for it, we re-investigated the possibility of a breakdown of PCr using gentler methods of extraction and more precise methods of analysis. These experiments showed that PCr in fact liberates creatine and inorganic phosphate during a single contraction[9,10,13,14] (Table 1). This finding has now been confirmed by Fleckenstein[15] and Mommaerts[16]. In normal rectus abdominis muscles of the female frog the inorganic phosphate and creatine content are sufficiently low (that is, 2·5 and 5·0 µmole/g) that changes can be observed during contraction, but the concentration of PCr is so high it is not possible to observe the expected changes with sufficient certainty. However, if the concentration of PCr is first lowered from about 12 to about 2·5 µmole/g by treatment with 2,4-dinitrophenol (DNP), (under conditions where the muscle can still do several complete contraction cycles) then the expected change in PCr can

Table 1. CHANGES IN INORGANIC PHOSPHATE (Pi) AND FREE CREATINE (Cr) IN NORMAL FROG RECTUS ABDOMINIS MUSCLES FOLLOWING ELECTRICAL STIMULATION AT 0° C

Type of exp.	Pairs of muscles	ΔPi (µmole/g muscle)	ΔCr (µmole/g muscle)	Average external work (g-cm/g muscle)	Length of stimulation (sec) (12 supramaximal pulses/sec)
Control-vs-activation	18	+0·08 ± 0·11	+0·11 ± 0·14	0–10	<0 2
Control-vs-shortening	9	−0·08 ± 0 20	+0 02 ± 0 21	0	0·5 − 1·0
Control-vs-contraction	21	+0·64 ± 0·14	+0·88 ± 0·20	120	1·0 − 2 5
Control-vs-contraction + relaxation + contraction	10	+1·20 ± 0·17	+1·22 ± 0·30	210	4·0 − 6·0
Control-vs-control	12	0·09 ± 0·10	0·29 ± 0 26	0	0 0
Contraction-vs-contraction + relaxation	7	+0·08 ± 0·14	— —	120*	1·0 − 2·5

* Both muscles of the pairs did the same amount of work.

The paired muscles from female *Rana pipiens* were dissected free, separated, and incubated in physiological bicarbonate saline solution at 25° C for 1–2 h. They were cooled to 0° C for 5 min and used as follows: In the activation experiments the muscles at rest length were stimulated and then frozen in liquid 'Freon' ($CF_2Cl_2 + CF_3Cl$) at −172° C as shortening began but before much external work had been done. In the shortening experiments the muscles were stimulated to shorten to one-half of their rest length under no external load and then frozen. Control–control values are for experiments in which neither member of the paired muscles was stimulated. Changes in Pi brought about by relaxation were studied by freezing one muscle at the height of 'after-loaded' contraction and permitting its pair to contract and then relax under load before being frozen. Muscles were extracted in aqueous methanol at −35° C for 7 days and the Pi and Cr measured by the methods of Wahler and Wollenberger[17], and Eggleton, Elsden and Gough[18]. Here and elsewhere, except when noted, all assays were done in duplicate. Results ± standard error of means.

Table 2. EFFECT OF ELECTRICAL STIMULATION IN HYPERTONIC SOLUTION AT 0° C ON THE PHOSPHORYLCREATINE (PCr) LEVEL OF FROG RECTUS ABDOMINIS MUSCLES

Pairs of muscles	No. of pulses (at 12/sec)	ΔPCr/pulse (µmole/g muscle)
4	12	0·00 ± 0·04
5	24	+0·01 ± 0 01
5	36	0 00 ± 0·01

These muscles were treated with 0·25 mM DNP at 20° C for 25 min and then for 20 min at 0° C in DNP-bicarbonate saline made hypertonic with 440 mM sucrose. Other conditions were as in Fig. 1. The work performed by these muscles was less than 3 g-cm/g muscle

Table 3. ASSOCIATION OF PHOSPHORYLCREATINE (PCr) BREAKDOWN WITH EXTERNAL WORK BUT NOT WITH DEGREE OF SHORTENING

Pairs of muscles	Per cent shortening $\frac{l_0 - l_s}{l_0} \times 100$*	ΔPCr (µmole/g muscle)	External work (g-cm/g muscle)	Stimulation time (sec) (12 pulses/sec)
Constant shortening—varying external work				
10	19·6 ± 2·24	−0·28 ± 0 15	21·7 ± 1·9	0·6 ± 0·1
10	20·2 ± 2 82	−0·36 ± 0·16	30·8 ± 2·3	1·2 ± 0·1
10	20·5 ± 2·27	−0·47 ± 0 26	46·6 ± 2·3	1·6 ± 0·2
8	21·1 ± 1·28	−0·58 ± 0 18	55·2 ± 0 9	2 0 ± 0·4
5	19·7 ± 3 13	−0·77 ± 0·24	64 2 ± 6·0	2 6 ± 0·5
Varying shortening—approx. constant external work				
11	10·7 ± 0·81	−0·44 ± 0·22	36 3 ± 4·7	1·9 ± 0·4
11	18·5 ± 0·75	−0·44 ± 0 16	37·3 ± 4·6	1·0 ± 0·2
11	23·4 ± 0·31	−0·48 ± 0·21	39 3 ± 5·1	1·2 ± 0·2
9	29·5 ± 1 08	−0·54 ± 0·11	50·8 ± 4·3	2 0 ± 0 4

*l_0 is rest length; l_s is length after shortening.

By varying the load, the muscles were made to do either different quantities of work while shortening the same amount, or the same amount of work while shortening to different lengths. The amounts of shortening and external work performed were determined from kymograph tracings. The muscles were treated as described in Fig. 1.

be observed to occur during a single contraction. The experimental techniques have been described previously[9,10,14].

The results are shown in Tables 1–3 and Fig. 1. It is clear that muscles made to do varying amounts of work broke down varying amounts of PCr to inorganic phosphate and creatine with a linear relationship between the amount of work and the amount of breakdown (Table 1, Fig. 1). Relaxation was not associated with any measurable change (Table 1). It is of interest that the observed breakdown of PCr is associated very much more with work than with either activation or shortening. The breakdown on activating the muscle and rapidly freezing it before it was allowed to do any work was quite small (Table 1). This was confirmed by stimulating the muscle in hypertonic saline (Table 2), where muscles are still activated but do not contract[20]. Similar small changes occurred in muscles which shorten against zero external load (Table 1). Furthermore, muscles performing an approximately constant amount of work with large changes in the degree of shortening showed no significant change in PCr breakdown associated with the shortening (Table 3), whereas for constant shortening and varying work a very clear correlation with breakdown of PCr was found (Table 3). Our direct chemical measurements show that in this muscle the breakdown of PCr can be associated with the work done and is rather independent of the amount of shortening that occurs.

It is of interest that DNP-treated muscles, which have low PCr but high creatine and inorganic phosphate, work with a reduced stoichiochemical efficiency (work per mole) (Tables 1 and 4, Fig. 1) which might well be expected on thermodynamic grounds.

In a mechano-chemical system the relation between output of heat and work done depends on the entropy and free energy of the chemical reactions, the efficiency of energy transduction and the absolute temperature. As Wilkie[21] has pointed out, when work is done by ATP usage under standard conditions at about 38 per cent efficiency, the reaction is thermally neutral. This type of situation may account for Hill's observation[22] of the striking appearance of work without extra initial heat production (above shortening heat) during the rising phase of a contraction, the time when we observe a breakdown of PCr. Assuming that results on sartorius muscles apply to rectus abdominis, our findings also show that the Fenn effect is to be expected; that is, " . . . when work is

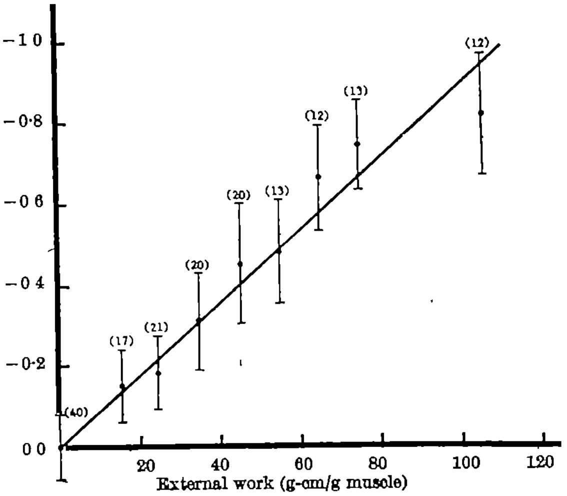

Fig. 1. Relationship of phosphorylcreatine breakdown to the amount of external work performed by 'after-loaded' frog rectus abdominis muscles contracting once or twice against a constant load to different degrees and for different times at 0° C. These muscles were isolated and incubated as described in Table 1, then treated with 0·25 mM DNP in bicarbonate saline solution for 40 min at 20° C and cooled to 0° C for 5 min. PCr was converted to creatinine by molybdate-catalysed acid hydrolysis and measured according to Barker and Ennor[19]. The figures in parentheses refer to the numbers of pairs of muscles used. Means ± *S.E.* Slope of line: 2,600 calories of external work/mole PCr

Table 4. PRODUCTION OF INORGANIC PHOSPHATE (Pi) WITHOUT CHANGE IN PHOSPHORYLCREATINE (PCr) AFTER THREE SMALL CONTRACTIONS AT 0° IN FROG RECTUS ABDOMINIS MUSCLES PRETREATED WITH DINITROPHENOL (DNP) PLUS FLUORODINITROBENZENE (FDNB)

Type of exp.	Pairs of muscles	External work (g-cm/g muscle)	ΔPCr (μmole/g muscle)	ΔPi (μmole/g muscle)

Control-vs-contractions	12	79 ± 8	− 0·17 ± 0 08	+ 1·23 ± 0 48
Control-vs-control	4	0	0 17 ± 0·17	— —
Control-vs-contractions (DNP but no FDNB)	4	76 ± 8	− 1·02 ± 0 28	— —

The paired muscles were isolated and incubated as in Table 1. They were then placed in bicarbonate saline solution containing 0·25 mM DNP for 30 min at 20° C followed by 20 min at 0° C in saline containing both 0·25 mM DNP and 0·38 mM FDNB. These salines were gassed with 5 per cent CO_2 + 95 per cent N_2. Total time of stimulation 4–6 sec.

Table 5. BREAKDOWN OF ADENOSINE TRIPHOSPHATE (ATP) TO FORM ADENOSINE DIPHOSPHATE (ADP) AND ADENOSINE MONOPHOSPHATE (AMP) DURING CONTRACTION OF FROG RECTUS ABDOMINIS MUSCLES AFTER TREATMENT WITH FLUORODINITROBENZENE (FDNB)

	ATP (μmoles/g muscle)	ADP (μmoles/g muscle)	AMP (μmoles/g muscle)
Single contraction			
Control	1·25	0 64	0·10
After 1 contraction	0 81	0·90	0·24
Change ± *S.E.* for 9 pairs	− 0·44 ± 0·046	+ 0·26 ± 0 023	+ 0·14 ± 0·027
Double contraction			
Control	1·24	0·61	0·07
After 2 contractions	0·59	0·88	0·41
Change ± *S.E.* for 3 pairs	− 0·65 ± 0 045	+ 0·27 ± 0 051	+ 0·34 ± 0 037

External work ≃ 100 g-cm/g muscle/contraction.

The muscles were isolated and incubated as described in Table 1 then treated with 0·38 mM FDNB for 40 min at 0° C. ATP, ADP and AMP were measured fluorometrically according to a modification of the method described by Estabrook and Maitra[30]. AMP results are based on single analyses. In some experiments, the ATP contents of control and contracted muscles were also measured by the use of the specific firefly luminescence technique with a photomultiplier coupled to a recorder[31].

done by the muscle, an extra supply of energy is liberated . . . which is roughly proportional to the work . . . "[23]. Thus there will be an extra heat output after the shortening while, *inter alia*, the PCr used by working muscle is being re-synthesized. However, the existence of shortening heat (apart from work heat) has recently been questioned[24] so the Fenn[23,25] effect might be directly related to the breakdown of PCr rather than to its re-synthesis.

Lundsgaard[4] showed, many years ago, that the energy for muscular work in a series of contractions could be directly related to the splitting of PCr, and this has recently been confirmed for large series of twitches[24,26]. However, it was not possible to determine whether the breakdown occurred during contraction or relaxation or whether the energy was delivered at the beginning or throughout the contraction cycle, whereas our experiments show that this chemical change occurs while the work is being done by the muscle. It is clear, and has been pointed out by Hill[27] and others, that the splitting of PCr is not proof of the breakdown of ATP. However, this breakdown should be observable if creatine phosphoryltransferase could be inhibited *in situ* and thus allow a direct demonstration of the primary role of ATP in muscular contraction. Kuby and Mahowald[28] had found that crystalline creatine phosphoryltransferase is completely inhibited by 1-fluoro-2,4-dinitrobenzene (FDNB), and we have now used this inhibitor to find the changes in ATP during single contractions which have been sought so often during the past thirty years[29]. When isolated muscles were pre-treated with FDNB, the number of normal contractions which could be performed was reduced from more than 30 to about 3, yet even when they would no longer contract, they still contained the normal quantities of PCr found in untreated muscle.

Table 4 shows that after treatment with DNP + FDNB, inorganic phosphate increased on contraction although PCr remained unchanged. Table 5 gives results with FDNB alone which show that ATP was split, but that the net amount of ADP produced was much less than the net ATP breakdown which itself was less than the inorganic phosphate production observed in the earlier experiments given in Table 1.

In these earlier experiments with normal muscles, the Lohmann reaction[5] was apparently the over-all energy-supplying mechanism; that is:

$$\text{ATP} \xrightarrow{\text{actomyosin ATPase}} \text{ADP} + \text{inorganic phosphate} + \text{work, and}$$

$$\text{PCr} + \text{ADP} \xrightarrow{\text{creatine phosphoryltransferase}} \text{ATP} + \text{creatine}$$

Thus, the changes in inorganic phosphate and creatine should be identical as is shown in Table 1. The apparent discrepancy shown in Table 5 can be resolved by consideration of the action of myokinase. This enzyme catalyses the reaction:

$$2\,\text{ADP} \xrightarrow{\text{myokinase}} \text{ATP} + \text{AMP}$$

Thus, the combined action of actomyosin ATPase and myokinase leads to the generalized equation given in Table 6. This generalized equation fits the experimental results remarkably well for both conditions tested. These findings, together with those we have obtained previously, demonstrate clearly and directly that the energy is delivered from a breakdown of ATP. They also make it clear that, in normal working muscle, creatine phosphoryltransferase makes available the energy stored in phosphorylcreatine, but that in extreme conditions myokinase can also be observed to operate in muscle.

Myokinase activity is important because by cyclic regeneration of ATP from ADP free energy is in effect released from the breakdown of both the labile phosphates of some of the ATP. The enzyme also maintains low levels of ADP, which is an inhibitor of myosin ATPase[32], and it keeps the ratio of ATP to ADP high. On thermodynamic grounds, this is advantageous for free energy liberation from ATP splitting.

Our results fit the sliding-filament theory[33]. If the tension-generating system depends on the formation

Table 6. STOICHIOMETRY OF THE CHEMICAL REACTIONS WHICH OCCUR DURING CONTRACTION AT 0° C OF FROG RECTUS ABDOMINIS MUSCLES TREATED WITH FLUORODINITROBENZENE

Generalized equation for the combined action of actomyosin ATPase and myokinase

$$n\ \text{ATP} \longrightarrow (n-m)\ \text{ADP} + m\ \text{AMP} + (n+m)\ \text{Pi}.$$

One contraction of frog rectus abdominis (All quantities in μmoles/g muscle)

$$(0\ 44 \pm 0{\cdot}046)\ \text{ATP} \longrightarrow (0{\cdot}26 \pm 0\ 023)\ \text{ADP} + (0{\cdot}14 \pm 0{\cdot}027)\ \text{AMP} + (0{\cdot}64 \pm 0\ 14)\ \text{Pi}^{*}$$

On the basis of the figures for ATP and ADP, the values calculated from the generalized equation are 0 18 AMP and 0 62 Pi.

Two contractions of frog rectus abdominis (All quantities in μmoles/g muscle)

$$(0{\cdot}65 \pm 0{\cdot}045)\ \text{ATP} \longrightarrow (0{\cdot}27 \pm 0{\cdot}051)\ \text{ADP} + (0{\cdot}34 \pm 0{\cdot}037)\ \text{AMP} + (1{\cdot}20 \pm 0{\cdot}17)\ \text{Pi}^{*}$$

The calculated values are 0·38 AMP and 1·03 Pi.

* Since we have not so far measured changes in ATP, ADP, AMP, PCr, Cr, and Pi all on the same muscle pairs, the changes in Pi are taken from the results on normal muscle given in Table 1.

of cross-links between the side branches of the myosin and the actin, then fewer links would be formed during rapid unloaded contractions and more would be formed during slow, working contractions. Thus different amounts of energy would be required. The demonstration that myokinase is operating during the actual contraction means that the same ATP can be used several times. Such a re-use of a small amount of ATP is consistent with the view that the side-branches must form bonds, develop tension, and break the bonds many times during a single contraction by a mechanism involving ATP splitting; it is inconsistent with the view that a given amount of ATP binds *on to the* muscle protein and causes a complete contraction by an entropic electrostatic mechanism[34]. In this case, the ATP would remain bound during the whole contraction and would only be released at the end as ADP + inorganic phosphate. Thus, neither ATP splitting nor myokinase action would occur during the contraction.

Our results strongly support the view that the shortening of muscle is due to the summation of effects caused by a small number of bonds which are formed and broken repeatedly. It follows that an ATP-dependent series of micro-entropic contractions of the myosin side pieces after they had linked asymmetrically with the actin might well account for the overall process of muscle contraction by the sliding filament mechanism.

In summary, these results show that, with frog rectus abdominis muscles when work is done, ATP is used during single contractions, and that this ATP is normally rapidly reconstituted by the action of creatine phosphoryltransferase and myokinase while the contraction is taking place. There is a linear relationship between the external work done and the cleavage of high-energy phosphate compounds, but very little energy from this source is required for activation and shortening *per se* in these muscles.

We thank Miss Dzintra Klaupiks, Messrs. W. J. Brunton and W. A. Eaton for assistance during part of this work.

This investigation was aided by U.S. Public Health Service grant *H*2520 and an American Cancer Society Institutional grant No. *IN* 38*D*.

NEWS and VIEWS

Controller of Rubber Research in Malaya: Sir Geoffrey Fletcher Clay, K.C.M.G., O.B.E.

Sir Geoffrey Fletcher Clay has recently retired from the post of controller of rubber research in Malaya, a position which he has held since 1958. Sir Geoffrey, a graduate of the Universities of Edinburgh and Cambridge, is well known as an agriculturalist. After the First World War he joined the Colonial Agricultural Service, spending many years in Uganda, where, in 1939, he was appointed director of agriculture. From 1942 until 1944 he was vice-chairman of the South African Production and Supply Council and from 1944 until 1946 development adviser for Northern Rhodesia and Nyasaland. For ten years, until 1956, he was agricultural adviser to the Secretary of State for the Colonies. Among his many other activities, Sir Geoffrey has been a member of the United Kingdom delegation to the conference organized by the United Nations on "Conservation of Resources" held at Lake Success in 1949. In 1952 he led the mission sent by the United Nations to Korea to prepare a five-year plan for the rehabilitation of Korean agriculture, forestry and fisheries. Sir Geoffrey has worked with the Food and Agriculture Organization on the problems of the reafforestation of the Mediterranean area, and has been closely associated with the Scientific Advisory Committee of the Empire Cotton Growing Association.

Dr. L. C. Bateman

Dr. Leslie Clifford Bateman has been appointed to succeed Sir Geoffrey Clay as controller of rubber research in Malaya. Dr. Bateman took up his position on August 1 and is now based in Kuala Lumpur. As controller he is responsible for the overall direction of the research and development programme for natural rubber carried out by the Rubber Research Institute of Malaya, the Natural Rubber Producers' Research Association and the Natural Rubber Bureau. Dr. Bateman was educated at Bishopshalt School, Uxbridge, and University College, London, where he gained honours in chemistry in 1935 and a Ph.D. in 1938, when he also won the Ramsey Memorial Prize for best student of the year. His postgraduate career included service as research assistant under Sir Christopher Ingold and Prof. E. D. Hughes and a senior studentship granted by the Department of Scientific and Industrial Research, held at Oriel College, Oxford, under Sir Robert Robinson. He received a D.Sc. at the University of London in 1955. He joined the then British Rubber Producers' Research Association as a physical chemist in 1941, and was promoted superintendent of chemical research in 1951, becoming acting director in 1953, and finally director of research in April 1954. Dr. Bateman has served the interests of the Natural Rubber Producers of Malaya for more than twenty years, and has been particularly successful in gathering around him a keen, enthusiastic and highly qualified staff at the Natural Rubber Producers' Research Association Laboratories at Welwyn Garden City, Herts. Dr. L. Mullins, at present deputy director of research at the Natural Rubber Producers' Research Association, will act as director during Dr. Bateman's absence, which will be for three years in the first instance.

Council for Scientific and Industrial Research

THREE new members of the Council for Scientific and Industrial Research have recently been appointed by the Minister for Science: Mr. W. J. Carron, president of the Amalgamated Engineering Union; Dr. S. C. Curran, principal of the Royal College of Science and Technology, Glasgow; and Dr. C. Sykes, deputy chairman and managing director of Thos Firth and John Brown, Ltd., Sheffield. They succeed the following, who have completed their term of office: Mr. L. T. Wright, general secretary of the Amalgamated Weavers Association; Dr. C. J. Smithells, past chairman of Magnesium Elektron, Ltd.; and Prof. B. Bleaney, professor of experimental philosophy in the University of Oxford, who has resigned from the Council on receiving a year's appointment at the University of Pittsburg.

The present constitution of the Council is: Sir Harold Roxbee Cox (chairman), Mr. L. H. Bedford, Mr. W. J. Carron, Prof. C. F. Carter, Dr. J. W. Cook, Mr. Frank Cousins, Dr. S. C. Curran, Mr. G. B. R. Feilden, Prof. E. R. H. Jones, Vice-Admiral Sir Frank Mason, Sir Harry Melville, Prof. O A. Saunders, Dr. C. Sykes and Mr. H. C. Tett.

Royal Society Visiting Professorships

PROF. R. DULBECCO, professor of virology, Division of Biology, California Institute of Technology, Pasadena, California, has been appointed Royal Society visiting professor for the academic year 1963–64. He is expected to take up the appointment in October 1963 and to work in the Departments of Genetics and of Virology at the University of Glasgow. Prof. Dulbecco is a leading virologist and has been the person chiefly responsible for the introduction of the quantitative analytical approach in the study of animal viruses. His interests lie in the three fields of virology, molecular biology and genetics.

The Royal Society and the Leverhulme Trust have established a scheme for the appointment of two visiting professors to India each year. Each visiting professor will visit a university or research institution in India for a period of about four months. It is hoped that in this way a contribution to higher education in India can be made. In implementing the scheme a committee in India will nominate the universities or other institutions to be visited; appointments will be made by the Council of the Royal Society, the finance and administrative arrangements being provided by the Leverhulme Trust Fund. The first appointments will be made so that the visiting professors can be in India during October 1963–February 1964.

The International Centre for Advanced Mediterranean Agronomic Studies

ON October 3, the Bari (Italy) Institute of the International Centre for Advanced Mediterranean Agronomic Studies, which was established under the ægis of the Organization for European Co-operation and Development and the Council of Europe, was officially opened. An inaugural lecture, on "International Co-operation and Economic Development", was given by the Italian Minister, Prof. Giuseppe Medici. The new buildings of the Bari Mediterranean Agronomic Institute, which have been built by the Italian Government, were officially opened on the same occasion. Forty students from countries in the Mediterranean area (Cyprus, France, Greece, Israel, Italy, Jordan, Malta, Morocco, Portugal, Spain, Syria, Turkey, Yugoslavia) are to attend the courses this year. Ten of them hold scholarships awarded by the Organization for European Co-operation and Development to nationals of member countries in the process of development. The others have received scholarships from the French and Italian Governments.

Cardio-respiratory Disease Research Project

THE London School of Hygiene and Tropical Medicine is to undertake a long-term research project on personal and environmental factors in cardio-respiratory diseases, including lung cancer, chronic bronchitis and coronary heart disease. The project has the support of the Tobacco Manufacturers' Standing Committee, which is to contribute up to £50,000 a year for ten years. This will also allow for a permanent endowment for the development of epidemiological studies at the School. The research project will have three main aims: (1) to investigate the various environmental factors, such as social, domestic and atmospheric conditions, affecting the onset and evolution of the commoner cardio-respiratory diseases; (2) to identify those physical and psychological characteristics, personal habits and those features of previous medical history which indicate a special predisposition to these diseases; (3) to study the interactions between these several factors, whether personal or external, in the production of cardio-respiratory disease.

It is planned to carry out surveys of the habits, health history and living conditions of different samples of the British population and to conduct physical examinations in smaller groups of individuals co-operating in this work. The later medical history of those taking part will then be carefully studied over a period of years. The whole project may take as long as ten years to complete, but some provisional results can be expected after four or five years. The honorary director of the project will be Prof. D. D. Reid, professor of epidemiology and director of the Department of Medical Statistics and Epidemiology at the London School of Hygiene and Tropical Medicine. Prof. Peter Armitage, professor of medical statistics at the School, will collaborate in this work, and the staff will be partly drawn from existing members of the Department and partly recruited specially for the project.

Films to Teach Science

SCHOOL science departments have, in the past, been hampered by the lack of specialized films suitable for use within the General Certificate of Education syllabus. To coincide with the beginning of the school year and the planning of new science courses, Sound-Services Film Library announces that it has been given distribution rights for the science teaching films of the Physical Science Study Committee produced by Educational Services, Inc. There are forty-eight titles in the 16-mm. film series, each film featuring well-known physicists who discuss and carry out experiments in a wide range of subjects. Apart from their use at the General Certificate of Education level, many will be of value to first-year university and technical college students. An illustrated brochure giving a synopsis of each film and an order form with details of hire and purchase charges can be obtained, free of charge, from Sound-Services, Ltd., Wilton Crescent, London, S.W.19.

Consolidating Fragile Iron Objects

THE conservation of objects, in which the iron has been completely converted to oxide, or in which only a small part of the metal remains as a slender core, has long been a problem to archæologists. In the September issue of the *Museums Journal* (62, No. 2; 1962) Messrs. R. M. Organ and P. Shorer describe an improved method for the consolidation of fragile iron objects. After a survey of the present methods, the authors advocate the use of a microcrystalline wax known commercially as 'Cosmolloid', whereby it is possible to consolidate an unstable object without prior stabilization and elimination of the ferric chloride. The grade 80 *H* is stated to be the most suitable for the purpose and the practical details are fully described in the paper quoted.

Nuclear Energy Research in Yugoslavia

THE first volume of papers from the Boris Kidrich Institute of Nuclear Sciences at Vincha appeared in July 1952, and until August 1953 the papers were published in the journal *Recueil de travaux de l'Institut de recherches sur la structure de la matière*. The title was then changed to the *Bulletin of the Institute of Nuclear Sciences 'Boris Kidrich', Belgrade*, and the *Bulletin* appeared annually with one volume per annum, except for 1953 and 1961, when two volumes per annum were published. During 1961 the number of papers submitted exceeded the possibility of the continuance of a standard volume per year, and accordingly with the commencement of Volume 13, 1962, the *Bulletin* is to be issued quarterly. The first issue (13, No. 1; April 1962) contains six articles, including a description of attempts made to measure the radiation of the *RA* reactor at Vincha by chemical dosimeters, and details of the '2*kC*' cobalt-60 radiation unit of the Boris Kidrich Institute at Vincha with its components—source, container, driving mechanism, radiation room, remote-control table, etc.

The Leopoldina German Academy of Science

THE Deutsche Akademie der Naturforscher Leopoldina, Halle, recently elected the following new members in the sections indicated: *Mathematics*, Prof. B. N. Delaunay (Moscow), Prof. Karl Marguerre (Darmstadt), Prof. Hans Reichardt (Berlin), Prof. I. M. Vinogradov (Leningrad); *Physics*, Prof. Hans Falkenhagen (Rostock); *Chemistry*, Prof. Oskar Glemser (Göttingen), Prof. Ulrich Hofmann (Heidelberg), Prof. František Šorm (Prague), Prof. Friedrich Wessely (Vienna), Prof. Georg Wittig (Heidelberg), Prof. S. Ju. Junusov (Taschkent); *Physical Chemistry*, Prof. Klaus Schäfer (Heidelberg); *Botany*, Prof. Paul Collander (Helsinki), Prof. Harry Godwin (Cambridge), Prof. Roger Heim (Paris), Prof. Bruno Huber (Munich), Prof. Poul Larsen (Bergen), Prof. Wilhelm Menke (Cologne), Prof. Heinrich Walter (Stuttgart-Hohenheim), Prof. Frits W. Went (St. Louis); *General Biology*, Prof. Ivan Málek (Prague), Prof. A. I. Tolmatchev (Leningrad).

Geology of the South-West of England

IN January 1956 a conference was held at the University of Exeter of geologists and geomorphologists working in the south-west of England. It was discovered that there was a real need for contact between the scattered workers who were pioneering new lines of attack on the little-known geology of this difficult region. A great deal of progress has been made in the past six years to which the subsequent conferences held in 1958, 1960, 1961 and 1962 have made a useful contribution. At the last conference a decision was taken to set up a properly constituted society to hold regular annual conferences each January and to publish the abstracts of the conference proceedings. Abstracts of the proceedings of the second, third and fourth conferences had been published by the kind offices of the Royal Geological Society of Cornwall. The new society is named the Ussher Society in honour of W. A. E. Ussher (1849–1920), an officer of the Geological Survey of Great Britain who made fundamental contributions to several aspects of the geology and geomorphology of the region.

The first conference of the Ussher Society as such will be held at the University of Exeter during January 2–4, 1963. The secretary is Mr. M. Stone, of the Department of Geology, University of Exeter.

The Night Sky in November

FULL moon occurs on Nov. 11d. 22h. 04m. U.T. and new moon on Nov. 27d. 06h. 30m. The following conjunctions with the Moon take place: Nov. 4d. 19h., Saturn 0·6° S.; Nov. 6d. 18h., Jupiter 1° N.; Nov. 18d. 09h., Mars 0·7° N. Mercury and Venus are too close to the Sun for easy observation. Mars rises at 22h. 20m., 21h. 55m. and 21h. 25m. on Nov. 1, 15 and 30, respectively. It is at a distance of 106 million miles on November 15, and its stellar magnitude is +0·5. Conditions are becoming more favourable for observation. Jupiter sets at 0h. 40m., 23h. 50m. and 22h. 50m. at the beginning, middle and end of the month, respectively. It is in Aquarius, its stellar magnitude is −2·1 and its distance from the Earth in the middle of the month is 436 million miles. Saturn is in Capricornus, setting at 22h. 00m., 21h. 10m. and 20h. 15m. on Nov. 1, 15 and 30, respectively. Its stellar magnitude is +0·9 and its distance from the Earth on November 15 is 947 million miles. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Nov. 6d. 17h. 38·8m., 50 Aqr. (*D*); Nov. 13d. 19h. 08·9m., 104 Tau. (*R*); Nov. 16d. 02h. 53·3m., 56 Gem. (*R*); Nov. 16d. 05h. 46·2m., 61 Gem. (*R*); Nov. 20d. 02h. 41·4m., 53 Leo. (*R*). There is also an occultation of Saturn visible at Greenwich: Nov. 4d. 19h. 23·4m. (*D*); Nov. 4d. 19h. 42·7m. (*R*). *D* and *R* refer to disappearance and reappearance, respectively. The Taurid meteors are active during the first two weeks of November. Conditions for observation are favourable; the radiant is near R.A. 3h. 36m., Dec. +14°. The Leonids are active during November 15–17, but conditions for observation are unfavourable.

Royal College of Science and Technology, Glasgow

The Royal College of Science and Technology, Glasgow, in consultation with the University Grants Committee, has appointed an Academic Advisory Committee. In the period of development ahead of the College, as outlined in the Government statement of May 1962, and pending the report of the Robbins Committee, the Advisory Committee will make available to the College its experience in developments both in Scotland and England. The terms of reference of the Advisory Committee will cover matters of general academic policy. The following are members of the Committee: Prof. E. L. Hirst, professor of organic chemistry, University of Edinburgh (*chairman*); Dr. Charles Wilson, vice-chancellor and principal of the University of Glasgow and lately vice-chancellor of the University of Leicester; J. O. Blair Cunynghame, deputy chairman of the Royal Bank of Scotland; Sir Lindor Brown, Waynflete professor of physiology, University of Oxford; Prof. J. Diamond, Beyer professor of mechanical engineering, University of Manchester; Prof. E. H. Phelps Brown, professor of economics of labour, London School of Economics; Prof. M. W. Thring, Newton 'Drew professor of fuel technology and chemical engineering, University of Sheffield; Dr. S. C. Curran, principal of the Royal College of Science and Technology, Glasgow.

John Wiley and Interscience Publications: Dr. F. Betz, jun.

Dr. Frederick Betz, jun., has been appointed to the editorial staff of John Wiley and Sons, Inc., New York, as editor in charge of the earth sciences and geography publications. He will be responsible for developing texts and reference books for the Wiley and Interscience imprints in the fields of geology, mineralogy, geophysics, meteorology, oceanography and geography. Since obtaining his Ph.D. from Princeton University in 1938, Dr. Betz has had varied experiences. He was associated for seventeen years with the U.S. Geological Survey, in the United States and in Europe, and also has served with the U.S. Bureau of Mines, the Newfoundland Geological Survey, the Department of Geology of Lehigh University, and the Geological Society of America.

Macmillan and Co., Ltd.: Mr. B. J. Walby

Mr. Basil J. Walby has joined the editorial staff of Macmillan and Co., Ltd., London, to succeed Mr. D. Grisewood, who has been appointed lecturer in mathematics in the Royal University of Malta. Mr. Walby will be responsible for scientific and technical books for secondary schools, technical colleges, universities, etc., published by Macmillan and Co. He read mathematics and chemistry at King's College, London, and then spent two years as senior science instructor in the College of the Rhine Army. For four years after he was assistant editor of *The Analyst* and of *Analytical Abstracts*, and then carried out research in industrial mathematics with particular reference to computer applications at the Distillers' Co., Ltd. More recently, Mr. Walby has been acting as a management consultant in operational research with SIGMA.

Announcements

Sir Geoffrey Taylor, formerly Yarrow research professor of the Royal Society of London, has been awarded the Franklin Medal of the Franklin Institute, Philadelphia, "for his manifold contributions to the knowledge of natural sciences".

Lord Hailsham, Minister for Science, is to open the new £2 million National Lending Library for Science and Technology at Boston Spa, Yorkshire, on November 5. The library collects all the world's literature of advanced science, technology and certain aspects of medicine, and promotes its use among industrial, agricultural and commercial organizations, universities and colleges, research institutes and hospitals throughout Britain. It has already amassed the largest scientific loan collection—at least 350,000 volumes—in Western Europe.

The second Western National Meeting of the American Geophysical Union will be held at Stanford University, California, during December 27–29. Further information can be obtained from the American Geophysical Union, 1515 Massachusetts Avenue, N.W., Washington 5, D.C.

The third Summer Research Institute of the Australian Mathematical Society will be held at the Australian National University, Canberra, during January 8–February 15, 1963, under the directorship of Prof. B. H. Neumann, of the Australian National University. Further information can be obtained from Dr. G. E. Wall, Department of Mathematics, University of Sydney.

The fifteenth technical exhibition of the Oil and Colour Chemists' Association will be held in the Old and New Halls of the Royal Horticultural Society, London, during March 11–14. Further information can be obtained from the general secretary, R. H. Hamblin, Oil and Colour Chemists' Association, Wax Chandlers' Hall, Gresham Street, London, E.C.2.

A meeting on "Questioned Document Examination", in conjunction with the third international meeting on "Forensic Immunology, Medicine, Pathology and Toxicology", will be held at the School of Pharmacy, London, during April 16–24. Topics under discussion will include: writing materials: paper, instruments, inks; laboratory examinations: chemical, photographical, optical; recent advances and problems in questioned document examinations; the role of the questioned document examiner as an expert witness. Further information can be obtained from the Secretariat (Q.D.), Third International Meeting in Forensic Immunology, Medicine, Pathology and Toxicology, 28 Portland Place, London, W.1.

Erratum. In the fourth paragraph of the article by Dr. A. Compton entitled "Effect of Feeding X-ray Irradiated Coliform Bacilli to Tumour-bearing Mice", which appeared on p. 1273 of the September 29 issue of *Nature*, the last sentence should read: "It may be viewed . . . graft tumours are known to grow as a rule not so well in older, larger animals[4]".

RESEARCH INTO MANAGEMENT

By Dr. STANLEY HYMAN

Department of Management and Production, Kingston College of Technology, Surrey

THE process of management operates wherever a group of people is working to achieve some purpose. Although most studies of management have been made within the context of private manufacturing business, it is a universal problem with considerable power to influence individual welfare and happiness. It is unfortunate, therefore, that there have been so few attempts to find out more about it through scientific research techniques.

Most of the work that has been done has been concerned with particular management 'tools', like work study, or with sociological aspects of management, such as the social class of managers or the impact of technical change on industrial relations. Controlled investigations of what managers do and think are extremely rare. It is obviously very difficult to investigate managers at work, if only because the presence of the investigator is likely to disrupt their normal behaviour. Self-analysis has been tried, but leaves one inevitably unhappy about the chances of having been told the full story—even when the informant wishes to hide nothing.

In an inquiry started last October, it seemed wise to begin on a different basis. To find out something about management, the obvious beginning was to talk to managers about their work. While this would not answer the methodological problems, it seemed a good thing to start with the simplest and most obvious source of knowledge that was immediately available. A questionnaire was prepared for completion at interviews, covering all the major aspects of the firm—its size and activities, form of ownership, numbers employed, products manufactured, numbers of customers, advertising expenditure, trade union relationships, research and development policy, membership of trade associations, and attitudes towards and knowledge of Kingston College of Technology. Respondents were also to be asked about the problems of their work which caused them the greatest concern.

It was appreciated that there were snags in this type of work and that the first batch of interviews could be no more than a pilot survey. When they were completed the whole project would have to be reviewed. We wrote to forty firms who were local members of the British Institute of Management or represented on the College's Management Advisory Committee. We explained briefly what we had in mind and asked for appointments. Thirteen did not reply and were not written to again. Seven others were interested, but for various reasons interviews did not take place. The other twenty were interviewed by three members of the staff of the Management Department—Mr. S. H. J. Freemantle, Mr. J. L. G. Mogford and myself. Usually two of us went to an interview, but sometimes there was only one interviewer, and in two cases there were three. Opinions differed as to the advantage of multiple interviewers—they may hinder ease of discussion.

It was realized that the firms visited were not necessarily representative of management in general —their special memberships testified to an unusual interest and perhaps serious attitude towards management. However, it was thought that this 'defect' would not matter in the pilot survey. The firms represented a wide range of industries and sizes (measured by numbers employed). Apart from one retail organization, they were all manufacturing firms.

The main results of the pilot survey were:

(1) The lengthy questionnaire was found to be largely useless for our purpose. It tended to regulate the conversation, even though we did not press the sequence of discussion to conform to the questions. After a few visits, we abandonded the questions and merely began by saying: "We would like to increase our knowledge of management, and it seemed wise to begin by talking to managers. Would you care to tell us what your major problems are?". Although some respondents were suspicious of our intentions at first, in no case was resistance found when we had explained our aims. In fact, the outstanding finding of these interviews is the eagerness of managers—and these were all general managers or directors—to talk freely about their jobs, their firms and their responsibilities. They gave us facts and figures and seemed unconcerned with secrecy although we had in fact promised to observe it. There was almost a psychotherapeutic need for them to talk in confidence to responsible outsiders, although from a psychological point of view most of these initial interviews remained superficial.

(2) Most of the factories visited were part of larger organizations. We were surprised to find how many, particularly among those whom we thought were independent. In some cases, we did not probe the precise ownership. Some of the firms had been bought up in 'take-overs', some had asked to be taken over, some were merely subsidiaries resulting from 'natural' growth. Apart from perhaps six independents, the operating unit that we visited was 'protected' by a larger headquarters, usually some distance away, that was said to allow very large amounts of discretion to the local manager, exept in matters of major policy such as capital investment.

We decided on the following programme for the major part of our research, tentatively planned to last five years.:

(1) A detailed survey of the industry and commerce in the area served by the College, in order partly to define the 'universe' we were dealing with and to construct a representative sample. The members of the sample would be visited and eventually we should be able to consider making valid generalizations about management, at least in our area. In these aims we would seek the aid of geographers and statisticians from other departments of the College. We would continue to make whatever visits we thought interesting until the 'universe' and sample were established, as that might take considerable time.

(2) We would seek further interviews with those of our initial survey who seemed especially valuable to us and who might be willing to give us perhaps another six hours of time to enable us to get a deeper and wider knowledge of their work, personalities and organizations.

(3) Two problems mentioned most frequently in the initial interviews were concerned with (*a*) the manager's lack of time to deal with all his duties properly, and (*b*) the apparent impossibility of finding competent subordinates to whom could be delegated a field of responsibilities with complete confidence. It seemed that these two problems were closely related to one another, but that some managers would have been sorry if a solution had been found. Managers are short of time partly because they cannot find subordinates. Hence the manager becomes increasingly indispensable and has no time to find and train subordinates. Hence he ceases seriously to ensure proper delegation. Hence the firm is dangerously dependent on his health, ability, adaptability and expectancy of working life.

(4) We formed a tentative hypothesis that a great deal of management problems were social in origin—coming from the society outside the firm—and that possibly a great number of benefits also came from these external sources. We thought that these external sources of help might be the substitute in the small firm for benevolent head offices in the large organizations. We propose, therefore, to investigate the role of local government, local offices of ministries, trade associations, the banks, and consultants, in helping or hindering managers in their work.

(5) We propose to make comparative studies of management outside the business firm. A beginning has been made with a hospital, and it is hoped to investigate the management problems of the professional practice, initially among architects.

THE UNDERGROUND LABORATORY OF THE NATIONAL CENTRE FOR SCIENTIFIC RESEARCH, FRANCE

FRANCE is one of the countries which has made a considerable contribution to the development of spelæology and biospelæology. An underground laboratory with modern equipment was developed after the Second World War, through the efforts of Profs. Jeannel and Fage and with the financial assistance of the National Centre for Scientific Research. A decree, dated February 11, 1948, specified that it should be built at Moulis, a small village in the Pyrenees, five kilometres west of Saint Girons. It took seven years to build, and was opened on June 26, 1954. The underground laboratory consists of a cave laboratory, which is equipped with low-voltage current and compressed air, and has a storage tank to collect the water of the underground stream running through it. The supply of water under pressure is ensured by a system of pumps and a hanging reservoir. The surface laboratory is some 300 yards from the cave, and includes laboratories, a library, bedrooms, a living room and a kitchen; the scientists are thus entirely independent. The original building has had an extra storey added to it and was considerably enlarged during 1960–61.

The laboratory was designed by zoologists and equipped for biological research. The cave laboratory is arranged so that cavernicolous animals can be raised there under optimum conditions, and investigations carried out *in situ*. It would be of great interest to carry out physical spelæology studies together with the biological investigations, as, for example, the study of the creation of underground cavities, the flow of underground streams and rivers, the composition of air and water in caves, underground meteorology, the creation and destruction of crystals and the composition of the clay found in the caves. A fuller knowledge of the physical media would, moreover, provide the biospelæologist with data of the highest value. For such work, however, specially equipped laboratories would have to be built and staffed with physicists and chemists. This will be a task for future generations.

Biospelæological research over the past fifteen years has dealt with three closely related problems: (1) the development and life-cycle of cavernicolous animals (worms, crustaceans, arachnids, insects, molluscs, fish and amphibians); (2) their metabolism; (3) their nutrition. The last-named has led to the birth of a new science, 'spelæobacteriology'.

One of the most serious gaps in biospelæological knowledge concerned the initial stages of cavernicolous life, about which little was known. Not only was survival of the animals made possible in the cave laboratory, but also almost all the species raised there also reproduced. The results obtained have been surprising and have justified the enterprise*.

Cavernicolous coleoptera can be divided into two main groups: Bathysciinae, which are omnivorous insects related to the Silphidae, and Trechinae, which are carnivorous insects related to the Carabaeid family. The way in which they have developed was unknown until recently. This problem has been resolved in the course of the past ten years by Mme. Glaçon-Deleurance's observations. There are several types of development of cavernicolous Bathysciinae, the degree of specialization of which is correlative to the 'cavernicolarity' of the insect. The peculiar cycle of the most cavernicolous of the Bathysciinae, such as *Speonomus longicornus*, was at first thought to be a deviation due to captivity. The initial results were soon confirmed, however, and there is now no doubt that the cycle observed in the laboratory is the same as that occurring under normal conditions.

In the most specialized species of Bathysciinae, the female lays only one egg at a time; this egg is extremely large and completely filled with vitellus. It hatches into a larva which has a short larval stage, (from a few hours to a few days). This explains why such larvæ had never been found in the caves, and were unknown until Mme. Glaçon-Deleurance carried out her observations. The larva rapidly builds itself a clay case in which it pupates. In the course of its brief larval life, the insect does not feed, grow or moult; it therefore has only one larval stage, whereas coleoptera normally moult twice and thus have three stages. The peculiar growth-cycle of this highly specialized species is related to the normal cycle by a series of intermediate species. Mme. Glaçon-Deleurance also resolved the problem of the development of Trechinae and, particularly, of

---

* *French Science News*, No. 1, January–March, 1962. (Paris: Ministère des Affaires Étrangères—Direction Générale des Affaires Culturelles et Techniques, 1962.)

Aphaenops, which is the most remarkable cavernicolous animal of the Pyrenean caves.

The comparative physiology of cavernicolous creatures and their epigeous counterparts was studied by Mme. Derouet-Dresco, who had worked with Prof. Fontaine. She has carried out research work on both aquatic crustaceans and spiders. In a remarkable thesis presented last year, M. R. Ginet mentioned that the growth of *Niphargus* is much slower than that of *Gammarus*, but that its life-span is far longer. After a comparison between the respiration-rates of epigeous spiders and the cavernicolous species, Mme. Derouet-Dresco showed that metabolism of the cavernicolous animals is less active than that of their closest biological relatives above ground, and can be compared with the metabolism of an ageing creature. This explains their extremely slow development and also their long life.

Biospelæologists have long suspected that the clay in the caves played an important part in the life of cavernicolous animals, either in their nutrition or in their reproduction and development. Research on the nutritional implication started when Rene Ginet carried out breeding tests with *Niphargus* in 1956. He showed that the young *Niphargus* continues to develop, for a certain length of time, in tanks containing clay but with no actual food of any sort, whereas when given food but no clay, all the young *Niphargus* die during their second moult. A research programme was therefore drawn up to investigate the properties of the clays.

Victor Caumartin, the co-ordinator of the research team, used an electronic microscope to discover a wide variety of bacterial flora in this underground clay, as well as certain types of porous rock, such as dolomite. One of his discoveries was a hitherto unknown ferrobacterium to which he gave the name of *Perabacterium spelai*. This bacterium is anærobic in its natural medium, and is completely autotrophic. It fixes the nitrogen of the air and gets its carbon from 'ferric carbonate'. The energy necessary for its metabolism is supplied by the decomposition of ferric carbonate, which frees ferrous oxide, and this in turn is transformed by oxidation into ferric oxide. When the supply of ferrous salts in the clay is exhausted the bacteria disappear and the clay becomes a strictly inorganic substance.

This remarkable bacterial species is the only one which has been studied in any detail, and its discovery sheds a new light on the clay found in these underground cavities. It is not only an inorganic mixture, but also a living medium which produces organic substances and can serve as food for cavernicolous creatures. The bacteria, and also the fungi, can synthesize the vitamins and growth substances which are normally supplied to animals by grass. This discovery shows the possible existence of a purely endogenous cycle within the depths of the Earth, to which no exogenous contribution is made. The closed cycle could be similar to that observed in the great marine trenches. Ginet and Miss Gounot give an initial, although tentative, insight into the interdependent nutrition cycles of the subterranean world.

The basic cycle is dependent on autotrophic bacteria and on ferro-bacteria in particular. A second, as yet incompletely known cycle is probably dependent on heterotrophic and saprophytic bacteria, and on various protista, amœbæ and flagellate zoospores. Limivora, such as Nematoda and Oligochæta, feed on this 'living clay' as do young *Niphargus* and *Proteus*. The Carnivora (adult *Niphargus* and *Planaria*) feed on Limivora. Finally, *Proteus*, which can be considered as a supercarnivore, feeds on *Niphargus* and *Troglocaris*. These cycles have as yet been observed only with aquatic animals, but it is probable that similar nutrition cycles govern the life of terrestrial cavernicolous animals.

THE BRITISH GELATINE AND GLUE RESEARCH ASSOCIATION

THE twenty-second meeting of the Research Panel of the British Gelatine and Glue Research Association was held on November 8, 1961, with the director of research, Dr. D. A. Sutton, in the chair.

Dr. F. S. Steven (University of St. Andrews) presented the first paper on his work with Dr. G. R. Tristram, entitled "The Presence of Non-Protein-Nitrogen associated with Soluble Calf Skin Collagen". It has been found that soluble collagen extracted by the acetic acid method and precipitated by sodium chloride contains a significant amount of non-protein nitrogen even after five successive dissolutions and precipitations. This 2 per cent of non-protein nitrogen material is left in solution when the collagen is adjusted to pH 11 and acetone is added, or it can be obtained by other procedures such as a combination of dialysis at pH 3·5 and acetone precipitation of the dialysate. It cannot be dialysed from the (precipitated) collagen at pH 7 nor does the addition of acetone free it at this pH. It would appear, therefore, that the non-protein nitrogen material is physically bound to the protein and it was shown by paper chromatography to contain eleven ninhydrin-positive components of which nine were amino-acids. Similar experiments were carried out with alkali-processed gelatines. The discussion centred round the possible bearing of these findings on the Courts and Stainsby multi-chain model for gelatin, since a relatively small percentage of amino-acids would cause a disproportionate drop in the found average chain weight as compared with the weight average molecular weight. Dr. Sutton pointed out that the authors' results were consistent with the supposition that only about 1 per cent of the non-protein-nitrogen material was amino-acid so that the bulk of it was presumably peptides, which would have a smaller effect on the ratio of chain weight to molecular weight.

The second paper, by Mr. N. T. Crosby and Dr. G. Stainsby (University of Leeds), "The Stability of Solutions of Solubilized Collagens", reviewed relationships between collagens extracted from skin in the cold by acid buffers and the soluble eucollagens which become extractable after skin has been soaked in cold alkali. The differences between the two groups are mainly quantitative, for example, soluble eucollagen preparations lie within a wider intrinsic viscosity-range and have slightly lower denaturation temperatures. Certain qualitative differences do exist, however, such as the absence of the 640 Å periodicity in reconstituted eucollagen fibrils and their lowered isoionic point arising from the loss of side-chain amide groups during the treatment with alkali. The accumulated data on eucollagens were discussed in the light of the most recent literature on the fine structure of soluble collagens. The subsequent discussion served to re-emphasize our present lack of knowledge on the number and nature of the inter-helix covalent links in insoluble collagens.

The final paper "Glueflok" by Dr. J. Wootton and Mr. W. B. Langston (British Gelatine and Glue Research Association), described experiments in which colloid-milled aqueous suspensions of cross-linked (insoluble) gelatines and animal glues were assessed as flocculating agents for a variety of suspensions, including quartz, colliery wash waters and paper fibres. Such suspensions were described by M. B. Goren and the name 'Glueflok' has now been proposed for them. The advantages of 'Glueflok' over soluble gelatine or glue are: (*a*) the formation of a much larger and more stable floc, (*b*) a three to ten-fold increase in flocculating efficiency, (*c*) independence of flocculating efficiency on *p*H over a wide range of *p*H and, (*d*) absence of resuspension when an excess is added. 'Glueflok' was also compared with the synthetic polyamide flocculating agents and efforts directed towards preparing it in the form of a dried powder were described. D. A. Sutton

THE NATIONAL CHEMICAL LABORATORY

THE report of the National Chemical Laboratory, 1961*, comprises the reports of the Steering Committee and of the director, Dr. J. S. Anderson, together with lists of sub-committees of the Steering Committee, staff in post at December 31, 1961, publications and patents in 1961, and of standard samples of organic compounds. The brief report of the Steering Committee, signed by the chairman, Dr. C. E. N. Bawn, records that after considering during the year the development of the Laboratory's research programme over the next five years, the Committee has planned for some growth of research, and in particular for continued development of the work in chemical thermodynamics over a period of years. The Committee agreed that in the field of corrosion of metals, the Laboratory's function should be to discover the fundamental processes underlying the complexity of corrosion phenomena, and work on the basic chemical and electro-chemical aspects of corrosion is to be strengthened accordingly, while the advisory work of the Group is to be continued. A more concentrated research attack in the inorganic-hydrometallurgical field is now planned for the Extraction of Metals Group, but, in consultation with the National Physical Laboratory Executive Committee, it has been agreed to dissolve the joint Pure Metals Research Sub-Committee. The Steering Committee is seriously concerned at the limitations on these developments which are imposed by the space at present available and a new site to enable additional accommodation to be provided is a matter of urgency.

The Director's report notes steady progress in implementing the Laboratory's revised research programme. During the year research on uranium and beryllium extraction, carried out on behalf of the Atomic Energy Authority, was continued, and now represents rather more than half the work of the Extraction of Metals Group, which has now been able to tackle some important fundamental problems that arise generally in hydrometallurgical work and in the chemistry of mineral processing; together with the Mineral Processing Group of the Warren Spring Laboratory, the Group constitutes a very powerful research team. The Inorganic Chemistry Group has discontinued work on the extreme purification of semi-conductor materials, and that on the separation of the rare earth elements is nearing completion. The work of finding significant technological outlets for materials that have become readily accessible is taking the Group into the field of solid-state science. As part of this development an X-ray Diffraction Unit has been set up. In chemical thermodynamics systematic measurements of the free energies and physicochemical properties of organic compounds, including heats of combustion, heat capacities at low temperatures, vapour compressibilities, vapour pressures and latent heats of vaporization and critical properties, is being carried out, but a comparable programme on inorganic materials is limited by lack of space. The Radioisotope Applications Unit continued to work in the Wantage Research Laboratory of the Atomic Energy Authority and, although short of staff, was able to initiate studies of the milling of coal to produce pulverized fuel for power stations, of the back streaming of oil from diffusion pumps using neutron-irradiated silicone oil, and of the uniformity of sizing of cotton yarn prior to weaving. Staff in post at the end of the year included 60 scientific officers and 7 research fellows; 111 experimental officers; 31 scientific assistants; 2 works technical officers; and 20 clerical and 43 industrial staff; the total authorized complement was 293 compared with 264 at the end of 1960.

In the Director's Research Unit several interesting features have emerged from an examination by field emission microscopy of the behaviour of small amounts of copper deposited by controlled evaporation on to a tungsten field emitter tip, and apparatus has been set up for the study of processes at the metal–gas interface with the field ion microscope. The New Materials Group has continued its thorough study of systems based on the $>BN<$ unit as a possible analogue of the $>C=C<$ unit in extended π-band systems, and the chemistry of aluminium nitrogen systems is being explored. The present objectives of work on organic semiconductors are examination of the possibility of synthesizing useful polymeric organic semiconductors and the study of the electrical properties of organic polymers in charge-transfer association with molecular species of high electron affinity. Progress is reported in the development of electron-exchanging polymers and the polymeric regenerable oxidants; this study has been extended to a more thorough polarographic investigation of the functional groups concerned while some progress is also reported in the study of high molecular organic semiconductors.

Basic research started during the year in the Extraction of Metals Group has been inspired either by difficulties or lack of knowledge encountered during applied hydrometallurgical investigations, or by ideas which could lead to major changes in hydrometallurgical processes. Under the general heading of the chemistry of leach liquors, the solution chemistry of silica is being investigated, and an investigation of the kinetics and mechanism of solvent extraction has been started. The extraction of beryllium from flotation concentrates continues to be the principal problem sponsored by the Atomic Energy Authority, and in the programme undertaken for the Authority, progress has continued in developing a contracting device whereby solvent extraction can be carried out directly on pulps or slurries without prior liquid/solid separation, and in the understanding of anion-exchange resins prepared from polyvinyl chloride, capable of absorbing uranium, but not silica, from acid solution. In the Inorganic Group a section has been set up to study the solid-state chemistry of rare earth compounds, and work has been commenced on comparative studies of chemical and catalytic activity, phase relations and physical properties of oxides and chalcogenides. Work on materials of interest as optical masers has involved exploratory studies of radically new kinds of matrix for excited transition metal ions, investigations of extremely pure alumina crystals and the role of impurities.

* Department of Scientific and Industrial Research. Report of the National Chemical Laboratory 1961: Report of the Steering Committee and Report of the Director. Pp. iii+75+4 plates. (London: H.M.S.O., 1962.) 5s. 6d. net.

The Corrosion of Metals Group reports that relatively simple techniques have yielded new information on the conditions in which the presence of different anions in solution inhibits corrosion, and relationships established for mild steel have been shown to apply also for zinc. Some indication has been obtained of the relative corrosion rates of several metals at high temperatures and pressures and measurements of corrosion rates and electrochemical studies continue to furnish information on the influence of different strains of bacteria on corrosion processes, while nutritional studies are being used to extend our knowledge of the biochemistry of the bacteria. Data that should lead to improved methods of estimating the relative aggressiveness of both soils and waters are being acquired. Attention has been directed to the sintering of evaporated metal films with the view of extending the fundamental work on oxidation, and in this connexion an investigation of the interaction of hydrogen with pure iron has yielded results of general interest.

ATOMIC ENERGY RESEARCH IN AUSTRALIA

THE ninth annual report of the Australian Atomic Energy Commission* covers the year ended June 30, 1961, in which capital expenditure was reduced by £174,458 to £1,229,542. With the completion of major buildings at the Research Establishment expenditure on construction fell substantially. There was an increase of £60,254, however, in the amount required for research plant and for equipment needed as the new buildings came into use and net current expenditure on research rose by £256,232 with the growth of staff and research activity.

The seven main sections of the report deal respectively with the development of the uranium industry in Australia during 1944–61; the search for uranium; uranium mining; raw materials; research; nuclear power; and general activities. The financial accounts and details of research contracts, postgraduate research studentships and the names of the staff of the Commission are given in appendixes to the report.

Production of uranium oxide at Rum Jungle was the highest for three years. Output of copper also increased. An important new ore-body was established at Rum Jungle Creek South, ore reserves being placed at about 600,000 tons of ore of an average grade of approximately 6·0 lb. uranium oxide per ton. There is no copper in this deposit. The three companies producing uranium oxide for sale under contract to the United Kingdom Atomic Energy Authority continued to operate successfully. Rewards totalling £14,000 were paid for three uranium discoveries. Reward payments for new discoveries have now been discontinued.

The Commission's Research Establishment at Lucas Heights is organized into a number of research sections, and an Operations Division which is responsible for the operation of the research reactors *Hifar* and *Moata* and for the engineering and administrative services. Research continued on the high-temperature gas-cooled reactor system of the thermal breeder type (*HTGCR*) based on a beryllium moderator in the form of a metal or oxide, and operating on a uranium–thorium fuel-cycle. This type of reactor is considered to offer excellent prospects for economical nuclear power in Australia in the decade 1970–80. By June 1961 the Establishment had commissioned most of the major equipment and buildings essential to the research programme. The reactor *Hifar* completed a full year of routine operation in September, when it was overhauled and afterwards run at a maximum power-level of 10 MW. The new low-power (10 kW) graphite and water-moderated reactor *Moata* became critical on April 10. It provides a neutron source for reactor physics experiments.

The effect of neutron irradiation on the physical and mechanical properties of beryllium metal is being investigated by irradiation at high temperatures and at *Hifar* reactor temperatures, followed by post-irradiation annealing. The main damage was revealed to be the formation within the metal of new atoms of the gases helium and tritium, leading to swelling and distortion of the metal. The effects of strain heat, temperature and heat-treatment on the mechanical properties of beryllium are also being studied. Other fuel materials being investigated include beryllium oxide; a cermet, consisting of a dispersion of mixed uranium and thorium oxide in beryllium; and graphite fuel mixtures. Methods are being developed for the recovery of valuable materials from irradiated *HTGCR* fuels. The Commission's chemical processing research effort has been concentrated on the problems of fuels containing beryllium, and on beryllium recovery and purification, and results have been most encouraging. A time-of-flight system is under construction for the measurement of the neutron energy spectrum from reactor cores and is under test on *Hifar*. A theoretical group has extended earlier simpler calculations of the uranium-233–

* Commonwealth of Australia: Australian Atomic Energy Commission. Ninth Annual Report for the year ended 30th June, 1961. Pp 84. (Coogee, N S.W. Australian Atomic Energy Commission, 1962.)

thorium–beryllium system to cover some aspects of burn-up and reactivity, but the full development of work on practical reactor behaviour must await better computing facilities.

Greater awareness in Australia of the potential of radioisotope applications is reported, and an increase is forecast in their uses in all fields, covering a wide range of techniques. However, in Australia radioisotope methods are still being used to a lesser extent than in other industrialized countries. Eighteen investigations were undertaken for outside organizations. In ten of these, radioisotopes produced in *Hifar* were used. Extensive assistance was given to the Hunter Valley Research Foundation in a study of silt movement in Newcastle Harbour. Other effluent tracer investigations were carried out for industrial organizations in New South Wales and Tasmania. A service was set up for labelling organic compounds with radioactive hydrogen (tritium). The long-term production of cobalt-60 for teletherapy use continued. At June 30, 1961, cobalt being irradiated had reached an estimated activity of 22,500 curies, of which approximately 80 per cent was at a sufficient strength for teletherapy use.

The main project of the small physics research group is the development, in conjunction with the Radiophysics Division of the Commonwealth Scientific and Industrial Research Organization, of a technique using radioisotopes to trace fine particulate matter in the atmosphere—namely, what happens to silver iodide when released at the base of a cloud. The Technical Physics Section evolved techniques for making solid-state α-particle detectors, using semiconductor materials, and research is being conducted into their performance and properties. Shortage of staff and laboratory space prevented much expansion of biological research; but some investigations have been made. In the section of the annual report dealing with health and safety it is reported that the quantity and variety of radioactive and toxic material stored and handled at the Research Establishment increased greatly during the year. Nevertheless, no person received a significant exposure to radiation or beryllium.

The Australian Institute of Nuclear Science and Engineering, with its headquarters at Lucas Heights, is an organization established jointly by the Commission and the Australian universities, and a portion of the annual report is devoted to its activities. The Establishment collaborated closely with the Institute in more than thirty projects, details of which are given in the report. An Institute Fellow was appointed to work at the Research Establishment on improving existing methods and developing new methods of using radioactive techniques in geological age determinations. The Commission awarded a number of undergraduate scholarships each year during 1954–57 as part of its plan to overcome a shortage of graduates in geology, geophysics, metallurgy and chemical engineering. A total of 28 students was awarded scholarships; the majority have since graduated and ten students were still undergoing training during 1960. Fifty-four separate research contracts have been awarded by the Commission to universities and hospitals in Australia, of a total value of £269,000.

S. WEINTROUB

UNIVERSITY ORGANIZATION IN INDIA

THE Proceedings of the Third Conference of the Vice-Chancellors of Indian Universities*, convened by the University Grants Commission and the Ministry of Education at New Delhi during October 28–29, 1961, include a notable inaugural address by Dr. K. L. Shrimali, Minister of Education, which indicates a striking contrast in the attitude of the Indian Government to universities compared with that of the South African Government. Dr. Shrimali was deeply concerned over recent events in Aligarh Muslim University and was fully aware that they represented a major failure of education, but it was for the universities themselves to correct this prejudice, intolerance and bigotry. They were not concerned solely with the training of minds but also with the education of emotions, cultivation of good taste and sense of decency and the development of character. Dr. Shrimali thought that the tutorial system could provide the answer to most problems, but, as free corporations, universities had the authority to make what changes they considered necessary to discharge their responsibilities to society, and a high sense of responsibility on the part of the universities was the essential condition for the preservation of their autonomy. Dr. Shrimali recognized that both Government and universities were liable to err, and it was their duty to correct each other, but the only way in a free society was to reach agreement through discussion. The whole temper of Dr. Shrimali's address was in line with Sir Eric Ashby's recent Chancellor's Lecture to the University of the Witwatersrand, and he urged that, more than money, to improve the quality of education are needed dedicated teachers who would stimulate thinking among the students, give them a vision of true greatness and inspire faith to dedicate themselves to the realization of great ideals.

The Proceedings also incorporate the address of Dr. D. S. Kothari, chairman of the University Grants Commission, on education and the universities, discussing the expansion of Indian universities. In this Dr. Kothari deals with the acute problem of student wastage and measures to reduce this and some proposals of the report on general education, such as refresher courses and seminars for a selected number of college and university teachers, the establishment of centres of advanced study on an all-India basis and promotion of academic mobility (for which purpose the universities must be bilingual, using English and the regional language). Establishment of about 12 new universities is envisaged during the Third Five Year Plan, issued in June 1961, to provide the anticipated additional 100,000 places required to keep pace with the expansion of the population. The Proceedings also include the recommendations of the Committee on Standards of Education, the Committee on Instruments of Education (dealing with entrance qualifications and tests for admission, training of teachers, quality and availability of university text-books, common calendar of terms, examination dates and publication of results and uniformity of standards) and the Committee on 'Emotional Integration', which considered the preparation of text-books, the role of student unions and the resolution of religious conflicts. It was recommended that all universities which make available a certain minimum number of places for students from other parts of India and those bearing denominational names should discard the denominational component of their title. The Committee on Standards of Education recommended an increase in the number of technical schools, polytechnics, trade schools, etc., and improvement of the student–teacher ratio to at least 1 : 7 or 1 : 10. English was considered the only appropriate medium of instruction in postgraduate education at present, and the Committee recommended that the University Grants Commission should play a more active part in the development of all higher education. Research centres should be built up around outstanding personalities.

THE CHALLENGE OF HUNGER

THE greatest challenge that faces mankind to-day and in the coming decades is the problem of feeding the growing population of the world. While the world population is increasing at an unprecedented rate, food production in the areas of the world where most people do not have enough to eat is lagging. Thus, to-day, mankind as a whole is not being adequately fed, and there is a population increase of such dimensions that by the end of this century—possibly earlier—the number of mouths to be fed will be more than double.

For several years the Food and Agriculture Organization of the United Nations has pointed out the dangers inherent in this situation. It has stressed that food production as a whole, but especially in the underdeveloped and developing countries, is not increasing fast enough. The rate of population-growth in the developing countries is more than 2 per cent, while the volume of agricultural production is increasing at slightly less than 3 per cent per annum —a margin that is clearly precarious. Any major set-back in agriculture in any part of the world, owing to climatic or other natural factors, could quickly wipe out the gains which have been so painfully won.

Statistics set out by Dr. Binai Ranjan Sen, the director-general of the Food and Agriculture Organization, reveal the realism of this warning. Estimates of world agricultural production in 1960–61 (excluding mainland China) show an increase of no more than 1 per cent over production in the previous season—which is less than the estimated rate of population growth of 1·6 per cent. If mainland China is included in the world agricultural production figures, the total production of 1960–61 would probably be less than that of 1959–60 instead of a 1 per cent increase. Set-backs due to bad weather in several regions of the world indicate that the 1961–62 production may again be small.

Since the Second World War there has been a great expansion in the production of food and agricultural products, but by far the largest part of this has taken place in Europe, in North America and Oceania. All these are countries where standards of living are high and the people are well fed and adequately nourished. In the food-deficient regions of Africa, Asia and Latin America, the increases have so far barely kept pace with the population increase. Thus, although the Far East Region, which is the worst nourished and most populous area in the world, has had a good harvest for three successive years and, excluding mainland China, the 1960–61 food production per head has only brought consumption levels up to those of 1939.

In other words, improvements in diets which could have been expected as a result of increases in food production have, in fact, been largely nullified by population increase. In Latin America, for example, *per capita* food production continues to lag behind pre-war levels. In the Near East, however, *per capita* production is now about 10 per cent greater than the low levels prevailing in the pre-war period. In Africa, a rather stationary situation prevailed with some ups and downs. These regional figures reveal wide differences among individual countries.

A statistical survey of the incidence of hunger and malnutrition was recently made by Dr. P. V. Sukhatme, director of the Statistics Division of the Food and Agriculture Organization, based on the international reference scale for calorie requirements and on the variation in energy expenditure among men of the reference age group. Applying the Food and Agriculture Organization calorie standards as a basis of comparison for the quantitative aspects of the diet, the study showed that calorie supplies in Europe, North America and Oceania are of the order of more than 3,100 calories *per capita* per day and exceed the requirements by about 20 per cent. In the Near East, Africa and Latin America, they are about equal to the requirements, amounting to some 2,400. In the Far East, the supplies are of the order of only 2,050 compared with a calorie requirement of some 2,300. The supply thus falls short of the requirement by 11 per cent.

This gap is particularly striking when compared with the total calorie supplies of other regions. Thus, the shortage in the Far East is of a quantity large enough to feed the entire population of the Near East. Even for other regions where the overall picture looks balanced, there are wide variations within the region. In the Near East, for example, there is apparently enough food in a group of countries where one-half of the population lives: the other half lives in a relatively poorer area. The calorie supplies of this area are only 2,100–2,200 *per capita* per day. It is therefore justifiable to conclude that many millions of people in the world still go hungry at least for a part of their lives.

Thus, the recent study conducted by the Food and Agriculture Organization* has shown that the gap of 11 per cent between the calorie supplies and the calorie requirements in the Far East is shared by one-fifth to one-fourth of the population of the region. Since this region comprises half the total world population, it is clear that a conservative estimate of the proportion of undernourished in the world is between 10 and 15 per cent. In actual numbers this means that between 300 and 500 million go hungry for part of their lives, even in normal times.

ELECTRON TRANSFER AND CARCINOGENESIS

By DR. ALBERTE PULLMAN and PROF. BERNARD PULLMAN

Institut de Biologie Physico-Chimique, Université de Paris,
13 Rue Pierre Curie, Paris

THE idea that electron transfer may be involved in chemical carcinogenesis was first proposed by us[1,2]. We postulated that the interaction of carcinogenic aromatic hydrocarbons with cellular receivers, which according to our general theory must occur through the *K* region of the hydrocarbons, involves the spreading out of the π electrons of the hydrocarbon into the bonds which unite the hydrocarbon to the cell. These bonds would then become partially double, the whole electronic cloud of the hydrocarbons assuming an approximately quinonoid configuration. The advantage of this hypothesis resides in the fact that it enables an interpretation of the metabolic transformations undergone by these carcinogens. Experimental results obtained by Bhargava and Heidelberger[3] seem to confirm the quinonoid nature of the bonds between the hydrocarbon and the tissue.

In our theory the existence of such an electron transfer between the carcinogen and the cell is dependent on certain electronic characteristics of the *K* and *L* regions of the carcinogens which constitute the primary conditions for the manifestation of carcinogenic activity. It may be added that within the series of carcinogenic molecules satisfying the primary conditions related to the *K* and *L* regions (aromatic hydrocarbons or methylbenzanthracenes) restricted correlations have been observed between carcinogenicity and the energy of the electronic transition to the lowest excited state or the ionization potential of the carcinogens[2,4].

Recently, a theory has been proposed which tries to link carcinogenesis with the possibility of an electron transfer in a more fundamental and specific way. Quantum mechanical calculations[5] having indicated the possibility of the existence of energy bands in proteins, Mason[6-9] has postulated that carcinogenic activity depends directly on the existence of an electron transfer from the highest filled band of the protein to one of the empty levels of the hydrocarbons. He postulated that in order for such a transfer to occur, an unfilled level of the hydrocarbon must match in energy with the highest filled level of the protein. Assuming that the highest filled molecular orbital of the hydrocarbon is at the same height as the bottom filled band of the protein, he arrives at the conclusion that in order to be carcinogenic an aromatic hydrocarbon must possess a transition energy in the range of 1·10–1·18, in units of β (the resonance integral of the usual Hückel approximation of the molecular orbital method).

It must be stressed in the first place that the basic physical hypothesis of Mason (the existence of a charge transfer from a protein to the hydrocarbon) is at present entirely arbitrary. Moreover, even if the principle of such a hypothesis is accepted, strong objections may be raised[10-14] to the model proposed by Mason. It has, in particular, been observed that according to the general theory of charge transfer complexes, the matching of energy-levels is not necessary for the formation of such complexes, which depend rather on the ionization potential of the donor and the electron affinity of the acceptor. It has also been observed that the adjustment of the energy-levels of the hydrocarbon and the protein should be made with respect to the free electron as energy zero and not by equating the energy of the lower filled band of the protein with the highest filled level of the hydrocarbon. Such equating leads to the erroneous prediction that the ionization potentials of aromatic hydrocarbons of the dimension of the carcinogens should be of the order of 11–12 eV, while most probably they are of the order of 7 eV [14]. Moreover, recent refined calculations on the possible energy bands in proteins[15-17] lead to results appreciably different from the older ones used by Mason.

In fact, stripped of its arbitrary and superfluous assumptions, Mason's proposition amounts simply to the existence of a correlation between carcinogenicity and the presence in a molecule of a transition energy between a filled and an empty orbital in the range $1{\cdot}10\beta$–$1{\cdot}18\beta$. The proposition is supposed to be valid whatever are the orbitals involved in the transition. Stated in this rigorous way the correlation scarcely has any physical significance. We wish to show, moreover, that the correlation is far from being as satisfactory as claimed by Mason.

Mason investigated 23 cata-condensed aromatics comprising 6 carcinogens and 17 inactive compounds. His criterion allows him to distinguish between the active and the inactive molecules, with two exceptions. When overlap is included in the calculations (in which case the 'active' range of the transition energies should be, following Mason, 1·248–1·348, in units of γ, the resonance integral with overlap) the exceptions are more numerous. To justify this result, Mason states[7] that the calculations without overlap have been shown to be somewhat better than the calculations with overlap in other investigations. This statement, however, is unfounded. Usually, the introduction of overlap does not change the general validity of the results. In problems involving the energies of the molecular orbitals and the transition energies of aromatic hydrocarbons, as is the case here, it definitely represents a refinement because it suppresses the degeneracy of the transitions.

In order to check the validity of Mason's proposed correlation we have extended the investigations to a series of other cata-condensed aromatic hydrocarbons, which have been investigated for carcinogenic activity. The compounds studied included the weakly carcinogenic 1,2,5,6-dibenzphenanthrene and 1,2,3,4-dibenzphenanthrene, the strongly - carcinogenic 1,2,3,4-dibenzpyrene, the very potent carcinogen 3,4,9,10-dibenzpyrene and fifteen inactive compounds. The results are indicated in Table 1, where it can be seen that Mason's correlation breaks down completely in these compounds. Thus, when the calculations are carried out without overlap, three carcinogens (including the extremely potent 3,4,9,10-dibenzpyrene) out of four have no transition energy in the 'active' range and, following Mason's criterion, should not be carcinogenic. On the con-

Table 1. TRANSITION ENERGIES IN AROMATIC HYDROCARBONS IN THE LIMITS OF MASON'S 'ACTIVE' RANGE

Compound	Transition energy Without overlap (in β units)	Transition energy With overlap (in γ units)	Carcinogenic activity
1,2,3,4-Dibenzphenanthrene	—	1·320, 1·334	+
1,2,5,6-Dibenzphenanthrene	1·100, 1·152	—	+
1,2,3,4-Dibenzpyrene	—	—	+ + +
3,4,9,10-Dibenzpyrene	—	1·319	+ + + +
1,2,6,7-Dibenzpyrene	1·110	1·296, 1·312	—
2′,3′-Naphtho-3,4-pyrene	—	1·327, 1·331	—
1,2,7,8-Dibenznaphthacene	—	1·252	—
1,2,9,10-Dibenznaphthacene	1·161	1,285, 1·297 1·329, 1·331	—
1,2,3,4-Dibenznaphthacene	1·102	1·276, 1·322	—
2,3,7,8-Dibenzphenanthrene	1·109	1·310	—
2,3,5,6-Dibenzphenanthrene	—	1·321	—
1,2-Benzpyrene	—	1·317	—
2,3,8,9-Dipenzperylene	1·115	1,263, 1·303 1·341	—
1,2-Benznaphthacene	1·172	1·267	—
2′,1′-Anthra-1,2-anthracene	1·135, 1·140	1·254, 1·299 1·314, 1·322	—
1′-2′-Anthra-1,2-anthracene	1·152	1·270, 1·294 1·318, 1·320	—
4,5,10,11-Di(1′,2′-naphtho)-crysene	1·178	1·253, 1·295 1·309, 1·316 1·343, 1·345	—
3,4,9,10-Di(2′,3′-naphtho)-pyrene	—	1,295, 1·313	—
Naphthodianthrene	1·177	1·276	—

trary, ten of the fifteen inactive hydrocarbons have a transition energy in the 'active' range and, following the same criterion, should therefore all be active. The disagreement between Mason's theory and experiment is even more striking when the calculations with overlap are taken into account: two carcinogenic hydrocarbons have a transition energy in the 'active' range, but this is also the case for all the non-carcinogenic compounds. A number of inactive compounds even have a few (up to six) transition energies in the limits of Mason's 'active' range. The only molecules which do not possess a transition energy in Mason's 'active' range are two carcinogens.

Mason has also included in his correlation a number of molecules other than the cata-condensed aromatics. There is no need to discuss this extension of Mason's theory here because it is obvious that it is very easy to find a great number of molecules of these other types which do not obey the correlation.

One of the foreseeable results of the attractiveness and at the same time arbitrariness of Mason's proposition was to give rise to a series of similar and just as unfounded propositions. Mason postulated electron-transfer from a protein to the carcinogen; Birks[12,18] suggests electron transfer in the reverse direction, from the carcinogen to the protein, and Ladik *et al.*[19,20] claim that the process may involve the nucleic acids rather than the proteins. At present none of these propositions has any acceptable basis. It may be said quite generally that the fact that, in the limited series of the carcinogenic hydrocarbons, restricted correlations may be established with some electronic characteristics such as the ionization potential or the transition energy to the first excited state cannot be of primary significance when a great number of non-carcinogenic hydrocarbons have the same characteristics. We may recall that the *K–L* regions theory of carcinogenesis, on the contrary, accounts satisfactorily for the activity or inactivity of practically all the aromatic hydrocarbons. The conditions imposed on the *K* and *L* regions seem thus to be the primary necessities for the existence of carcinogenic activity. On the other hand, the hypothesis that a 'local' electron transfer may be involved in carcinogenesis has found some experimental confirmation in the recent work of Szent-Gyorgyi *et al.*[21] on the formation of charge transfer-complexes between carcinogens and iodine. The involvement of such a transfer in carcinogenesis is, however, subject to the fulfilment of the primary conditions for the interaction between the carcinogen and the cellular receiver, based on the characteristics of the *K* and *L* regions.

This research was supported by grant *CY* 3073 of the United States Public Health Service (National Cancer Institute).

CHEMICAL HETEROGENEITY OF HÆMOGLOBIN O

By DR. C. BAGLIONI*

Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts

AND

DR. H. LEHMANN

Department of Pathology, St. Bartholomew's Hospital, London, E.C.1

WE wish to report on two samples of hæmoglobin O (Hb–O), characterized by identical electrophoretic and chromatographic properties. Hb–O has first been described in Indonesia by Lie-Injo Luan Eng and Sadono[1]. Ramot *et al.*[2] have since reported the occurrence of Hb–O in an Arab family, in which hæmoglobin S (Hb–S) was also observed. In this family the Mendelian inheritance of the gene responsible for Hb–O was also shown.

Two samples of blood containing Hb–O have been examined: sample I came from an Indonesian woman seen in London and one may presume that the Hb–O

---

* Present address: International Laboratory for Genetics and Biophysics, Via Claudio 1, Naples.

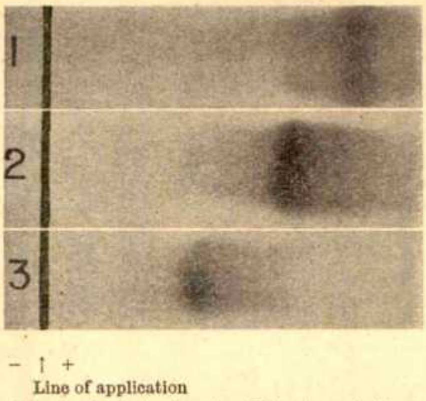

Fig. 1. Starch-gel electrophoresis of the hæmoglobins isolated from sample II. 1, Hb-F; 2, Hb-S; 3, Hb-O$_{\text{Ar}}$

of this individual may be identical with the type described by Lie-Injo Luan Eng and Sadono[1]. Sample II came from a member of the Arab family described by Ramot *et al.*[2], namely the sister of the propositus. We will refer to the Hb–O in samples I and II as Hb–O Indonesia and Hb–O Arab (Hb–O$_{\text{Indon}}$ and Hb–O$_{\text{Ar}}$) respectively.

The two samples were subjected to preparative column chromatography on carboxymethylcellulose according to the method of Huisman and Meyering[3]. The identity and the purity of the hæmoglobins eluted from the columns were determined by starch-gel electrophoresis according to Poulik's method[4] after concentration on small columns of carboxymethylcellulose. Two hæmoglobins were isolated from sample I; they were shown by starch-gel electrophoresis to be hæmoglobin A (Hb–A) and Hb–O$_{\text{Indon}}$. Three hæmoglobins were isolated from sample II: fœtal hæmoglobin (Hb–F), Hb–S and Hb–O$_{\text{Ar}}$. Hb–F was eluted as the first and Hb–O as the last peak. The starch-gel electrophoresis of the hæmoglobins isolated from sample II is shown in Fig. 1.

No Hb–A was found in sample II. Ramot *et al.*[2] had found Hb–A as well as the abnormal adult hæmoglobins Hb–O and Hb–S in the propositus and his sister. When this newly obtained sample was now found to contain no Hb–A, the propositus was re-examined and again no Hb–A was found on this occasion. A careful search for evidence of a previous blood transfusion had been made by Ramot *et al.*[2] before they accepted the finding of three adult hæmoglobins A, O and S as representing a genuine blood dyscrasia, and a transfusion had also been strenuously denied by the parents of the children. However, in view of the present observations, it must be assumed nevertheless that the children had been transfused at some time when the nomadic family had been receiving medical care before they were seen in Israel and that the third adult hæmoglobin – A was an acquired and not an inherited character.

The hæmoglobins isolated were heat-denatured and digested with trypsin and the tryptic digests were analysed by 'fingerprinting' according to Ingram[5], using the different chromatographic solvent described by Baglioni[6]. The pattern of the tryptic peptides of Hb–O$_{\text{Indon}}$ was found to be identical to that obtained from Hb–A. The absence of any detectable difference in the pattern of the soluble tryptic peptides suggested that a chemical difference could possibly be found among the insoluble peptides obtained by tryptic digestion, which are removed by centrifugation prior to fingerprinting. It has been shown by Hunt and Ingram[7] that after tryptic digestion about one-third of the hæmoglobin molecule (the so-called 'core') is insoluble at neutral *p*H.

The cores of Hb–A and of Hb–O$_{\text{Indon}}$ were isolated, digested with chymotrypsin and fingerprinted. The pattern of peptides obtained from these two cases were found to differ. In the Hb–A core fingerprint two spots give a strong positive reaction for histidine when tested with the Pauly reagent; these two spots were found to be missing in the Hb–O$_{\text{Indon}}$ core fingerprint. One histidine-positive spot was observed in the Hb–O$_{\text{Indon}}$ core fingerprint which was not present in the Hb–A core fingerprint; this spot is indicated by an arrow in the Hb–O$_{\text{Indon}}$ core fingerprint shown in Fig. 2.

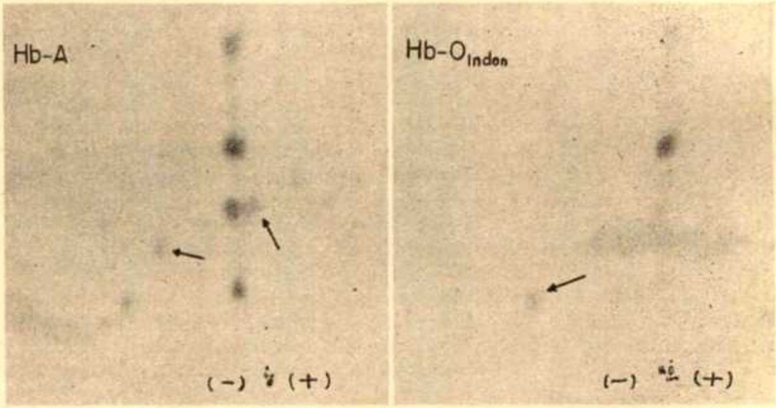

Fig. 2. Fingerprints of the chymotryptic digests of the cores of Hb-A and of Hb-O$_{\text{Indon}}$. The arrows in the Hb-A core fingerprint indicate the two peptides missing in Hb-O$_{\text{Indon}}$ core fingerprint. The arrow in Hb-O$_{\text{Indon}}$ core fingerprint indicates the extra peptide, which gives a positive reaction for histidine

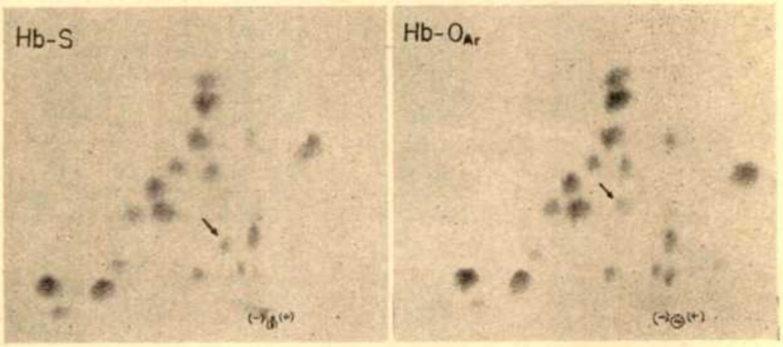

Fig. 3. Fingerprints of the tryptic digests of Hb-S and of Hb-O$_{\text{Ar}}$ isolated from sample II. Arrows indicate the abnormal peptides characteristic of these two hæmoglobins

The core was also prepared from isolated α- and β-chains of Hb–A, donated by Dr. Michael Naughton, Division of Biochemistry, Massachusetts Institute of Technology. They were digested with chymotrypsin and fingerprinted[7,8]. It was shown that the two peptides missing in the Hb–O$_{\text{Indon}}$ core fingerprint correspond to two peptides obtained from the α-chain core; no peptides occupying the same position in the peptide map have been observed in the fingerprint of the β-chain core. It thus seems likely that a chemical difference exists between Hb–A and Hb–O$_{\text{Indon}}$ in that part of the amino-acid sequence of the α-chain corresponding to the core, that is, from residue 100–139.

The hæmoglobins isolated from the Arab child were also fingerprinted. The peptide patterns of Hb–F and Hb–S were found to correspond to the pattern described by Hunt[9] and Ingram[5] for these hæmoglobins. In the Hb–O$_{\text{Ar}}$ fingerprint one peptide was seen to have moved from the band containing uncharged peptides to a new position nearer the cathode. This peptide gave a positive reaction for tyrosine and was identified as peptide 5. In Fig. 3 are shown the fingerprints of Hb–S and Hb–O$_{\text{Ar}}$ obtained from sample II; the peptides altered in Hb–S and Hb–O are indicated by arrows.

A peptide pattern somewhat similar to that observed in Hb–O$_{\text{Ar}}$ has been described by Benzer, Ingram and Lehmann[10] for one type of Hb–D, designated first as Dγ and later as D$_{\beta\ \text{Punjab}}$. Bowman and Ingram[11] have examined an unrelated sample of Hb–D showing the same peptide pattern and have localized the peptide alteration in the β-chain of this hæmoglobin. In a recent investigation by Baglioni[12] several samples of Hb–D were shown to be identical to this type of hæmoglobin D. In this hæmoglobin the glutamic acid residue in position 121 of the β-chain of Hb–A is substituted by a glutamine residue.

The peptide altered in the Hb–O$_{\text{Ar}}$ has been prepared by high-voltage electrophoresis and paper chromatography, following the same procedure which was used to isolate the peptide in Hb–D$_{\beta\ \text{Punjab}}$. The amino-acid composition of the peptide altered in Hb–O$_{\text{Ar}}$ designated peptide O$_{\text{Ar}}$–5, of D$_{\beta\ \text{Punjab}}$–5, and of A–5 are shown in Table 1; the analysis of peptides A–5 and D$_{\beta\ \text{Punjab}}$–5 have been reported previously[12].

Peptide O$_{\text{Ar}}$–5 shows the presence of two glutamic acid residues instead of the three found in peptide A–5. The *N*-terminal amino-acid of peptide O$_{\text{Ar}}$–5 has been determined by Sanger's method (1955); dinitrophenyl phenylalanine was identified by two-dimensional paper chromatography according to Frankel-Conrat *et al.*[13]. The results of the *N*-terminal amino-acid determination and of the sequence studies on peptides A–5 and D$_{\beta\ \text{Punjab}}$–5 previously reported are shown in Table 2.

The results of the amino-acid analysis of peptide O$_{\text{Ar}}$–5 and of the *N*-terminal amino-acid determination suggest that the residue corresponding to the *N*-terminal glutamic acid of A–5 is missing in O$_{\text{Ar}}$–5. This finding can only be accounted for by a substitution of an arginine or a lysine residue in Hb–O$_{\text{Ar}}$ for the glutamic acid occupying position 121 in Hb–A. The peptide bond between the arginine or lysine and the phenylalanine in position 122 could be split by trypsin, and phenylalanine, which is the second residue in peptide A–5, becomes the *N*-terminal of peptide O$_{\text{Ar}}$–5. No free arginine has been observed in the fingerprint of Hb–O$_{\text{Ar}}$; one would expect free arginine to be released from a . . . Lys. Arg. Phe . . . sequence. Most likely the glutamic acid in position 121 is substituted by a lysine residue in Hb–O$_{\text{Ar}}$. This substitution accounts for the difference in electrophoretic mobility between Hb–A and Hb–O$_{\text{Ar}}$; Hb–O$_{\text{Ar}}$ migrates on paper or starch electrophoresis close to Hb–C and Hb–E, in which as Hunt and Ingram[14] have shown a lysine residue replaces a glutamic acid residue. It is noteworthy that two different substitutions have been found to involve residue 121, in Hb–O$_{\text{Ar}}$ and in Hb D$_{\beta\ \text{Punjab}}$. A similar situation has been previously observed for Hb–S and Hb–C; a valine in Hb–S and a lysine in Hb–C substitutes for a glutamic acid in position 6 of the β-chain of Hb–A[14].

Table 1. AMINO-ACID ANALYSIS OF PEPTIDE A-5, D$_{\beta\ \text{Punjab}}$–5, AND O$_{\text{Ar}}$–5

	A-5	D-5	O$_{\text{Ar}}$–5
Threonine	0·95	0·89	0·94
Alanine	2·16	2·16	1·85
Glutamic acid	2·84	2·88	1·87
Proline	1·97	2·14	2·14
Valine	1·15	0·93	1·27
Tyrosine	0·71	0·64	(0·13)
Phenylalanine	1·01	1·14	0·91
Amount of peptides (μM)	0·26	0·07	0·24

The molar ratio of the amino-acids is given, and the peptides are defined as βTp XIII according to the recommendations for the nomenclature of hæmoglobins by Gerald and Ingram (ref. 18).

The two samples of Hb–O examined carry chemical alterations in different parts of the hæmoglobin molecule: Hb$_{\text{Indon}}$ in the α-chain and Hb–O$_{\text{Ar}}$ in the β-chain. Chemical heterogeneity of hæmoglobins, which behave identically on chromatography and electrophoresis, has previously been shown by Benzer *et al.*[10]. Three samples of Hb–D obtained from unrelated individuals living in different countries were found to carry chemical changes in different parts of the molecule. Three samples of Hb–G have also been shown to carry different chemical changes[15–17]. According to Gerald and Ingram's[18] recommendations for the nomenclature of hæmoglobins, Hb–O is defined as $\alpha_2^A\ \beta_2{}^{121\text{Lys}}$.

While this work was in progress yet a third example of Hb–O was found by Lehmann and Vella[19], this time in the Sudan. They studied this sample by hybridization methods and found it to be a β-chain abnormal hæmoglobin. They direct attention to a possible anthropological significance of hæmoglobin O,

Table 2. SEQUENCES OF PEPTIDES A-5, D$_{\beta\ \text{Punjab}}$–5 AND O$_{\text{Ar}}$–5

Residue No. in the β-chain of Hb-A	121 —	122 —	123 —	124 —	125 —	126 —	127 —	128 —	129 —	130 —	131 —	132
A-5	Glu	Phe	Thr	Pro	Pro	Val	NH_2 | Glu	Ala	Ala	Tyr	NH_2 | Glu	Lys
D$_{\beta\ \text{Punjab}}$–5	NH_2 | Glu	(Phe	Thr	Pro	Pro	Val	NH_2 | Glu	Ala)	Ala	Tyr	NH_2 | Glu	Lys
O$_{\text{Ar}}$–5		Phe	(Thr	Pro	Pro	Val	NH_2 | Glu	Ala	Ala	Tyr	NH_2 | Glu)	Lys

The sequences of residues in brackets have not been determined.

one abnormal in the α-chain found in an Indonesian and presumably the same Hb–O as that seen by Lie-Injo Luan Eng and Sadono[1] in that part of Asia, and the other Hb–O abnormal in the β-chain, and seemingly associated with Arabs.

We thank Dr. V. M. Ingram for his help, Dr. B. Ramot for the samples of Hb–O_{Ar} used in this work, Dr. M. A. Naughton for providing us with the isolated chains of hæmoglobin A, and Miss Marianne Schick, who performed the quantitive amino-acid analysis. This work was supported by grants of the National Institute of Health (*A* 3409) and of the National Science Foundation (*G* 9764).

CHROMOSOMAL REARRANGEMENTS AND THE EVOLUTION OF HAPTOGLOBIN GENES

By O. SMITHIES, G. E. CONNELL and G. H. DIXON

Department of Medical Genetics, University of Wisconsin, and Department of Biochemistry, University of Toronto

THE three common types of haptoglobin (Hp 1–1, 2–1 and 2–2)[1–3] have recently been divided into a total of six types (Hp 1F–1F, 1F–1S, 1S–1S, 2–1F, 2–1S and 2–2)[4] on the basis of electrophoretic differences in their component polypeptide chains dissociated by treatment with a thiol in the presence of urea. Family studies[5] indicate that these types are the expression of the combinations of three alleles, Hp^{1F}, Hp^{1S} and Hp^{2}, each of which gives rise to the production of a corresponding polypeptide chain (hp 1Fα, hp 1Sα and hp 2α). All haptoglobins contain an additional polypeptide chain, the β-chain, which appears to be unaffected by the genotype at the *Hp* locus.

Structure of haptoglobin α-polypeptide chains. The results of our investigations[6] of the differences between the three common haptoglobin α-polypeptide chains may be summarized in part as follows: Amino-acid analyses of hp 1Fα and hp 1Sα suggest the replacement of a single lysine residue in hp 1 Fα by an acidic amino-acid (or its amide) in hp 1Sα. In agreement with these analyses we find that the peptides obtained from hp 1Fα and hp 1Sα after chymotryptic digestion are indistinguishable by finger-printing[7] except for the replacement of one peptide (F) in hp 1Fα by another peptide (S) in hp 1Sα. The effect of *p*H on the mobilities of the α-chains and the native haptoglobins is also consistent with the substitution of a basic amino-acid in hp 1Fα by an amidated acidic amino-acid in hp 1Sα. On the other hand, although the amino-acid composition of hp 2α is very similar to the compositions of hp 1Fα and hp 1Sα, the peptides obtained from hp 2α differ from those obtained from hp 1Fα and hp 1Sα (Fig. 1) more extensively than can be accounted for by amino-acid substitutions. Thus, all peptides present in digests of hp 1Fα and hp 1Sα are found in digests of hp 2α together with an extra peptide (*J*); two peptides (*N* and *C*), which are common to all three α-chains, are relatively deficient in hp 2α. The amino-terminal amino-acid of peptide *N* and of the whole α-chains is valine, and the carboxy-terminal amino-acid of peptide *C* and of the whole of α-chains is glutamine, which suggests that these peptides originate from the ends of the α-chains. Amino-acid

Fig. 2. Outlines of the proposed structures for the three common haptoglobin α-polypeptide chains showing their characteristic features. The order of peptides F and S in hp 2α is arbitrary and could be reversed. The arrows indicate points of attack of chymotrypsin. Amino-acids at the ends of the chymotryptic peptides have been determined by the dinitrofluorobenzene and carboxypeptidase methods; amino-acids in parentheses are present in the corresponding peptides but their positions are not known

analyses of the peptides *N*, *C* and *J* and examination of the peptides obtained from them by further enzymatic digestion with subtilisin or trypsin, suggest that *J* is slightly smaller than the peptide which would be obtained by joining *C* and *N* with a peptide bond. Peptide *J* has the same amino-terminal amino-acid (isoleucine) as *C*, and the same carboxy-terminal amino-acid (tyrosine) as *N*. Furthermore, almost all our preparations (see following) of the polypeptide hp 2α show both the peptides (*F* and *S*) characteristic of hp 1Fα and hp 1Sα. These finding are understandable if almost the whole of the amino-acid sequence of the hp 1α polypeptides occurs twice in a single molecule of hp 2α, and lead us to suggest the structures for the three haptoglobin α-polypeptides shown in outline in Fig. 2.

The general correctness of the proposed structures has now received confirmation from measurements of the molecular weights of the α-chains, and of the yields from them of *N*-terminal amino-acid (valine) and of C-terminal amino-acid (glutamine), as shown in Table 1.

Table 1

	Molecular weight*	*N*-valine† (per mg)	*C*-glutamine‡ (per mg)
hp 1Fα	8,860 ± 400	0·034 μM	0·063 μM
hp 1Sα		0·035 μM	
hp 2α	17,300 ± 1,400	0·021 μM	0·032 μM

* By Archibald method.
† By dinitrofluorobenzene method, uncorrected for losses during hydrolysis and chromatography.
‡ By carboxypeptidase method, uncorrected.

Evolution of haptoglobin genes. The substitution of one amino-acid residue in hp 1Fα by a different residue in hp 1Sα indicates that the genes Hp^{1F} and Hp^{1S} may differ only in a single base pair, as has been suggested for the genes controlling the hæmoglobin variants *A*, *S*, *C*, etc.[8]. On the other hand, the structure of hp 2α, in which most of the amino-acid sequence of the hp 1α polypeptides is repeated in a single molecule, indicates that the gene Hp^2 did not evolve from Hp^{1F} or Hp^{1S} by mutations involving small changes in base composition. The simplest hypothesis we can suggest (outlined in ref. 6) is that the gene Hp^2 was evolved from Hp^{1F} and Hp^{1S} by non-homologous crossing-over occurring in a heterozygous individual Hp^{1F}/Hp^{1S}. The suggested mechanism is illustrated diagrammatically in Fig. 3, and is similar to the type of process proposed by Serebrovsky[9] to account for chromosomal rearrangements in general. The net result of this non-homologous crossing-over is the production of one chromosome containing a small duplication and one with a corresponding deletion.

Chromosomal rearrangements and gene evolution. Duplication of existing genes as an important factor in evolution has been discussed previously by several workers (for example, Bridges[10], Lewis[11], and Ingram and Stretton[12]), but the consequences at the molecular level of *partial* gene duplications do not appear to have been foreseen. Our studies with the haptoglobin system indicate that partial gene duplications can lead to the production of a continuous polypeptide which 'bridges' the beginning of the duplication. We use the term 'gene' here, and in what follows, to mean that portion of the DNA coded for a single polypeptide chain, such as an α-chain of haptoglobin. No assumptions as to the length or nature of the DNA between such genes are

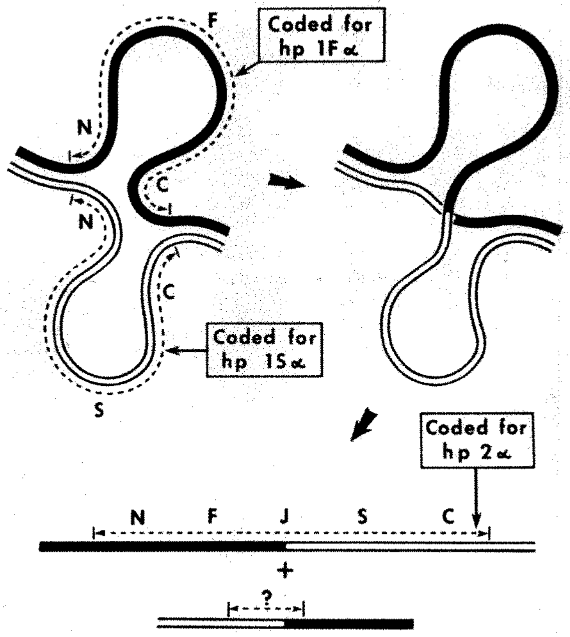

Fig. 3. Diagrammatic representation of the possible evolution of the gene Hp^2 from Hp^{1F} and Hp^{1S} by non-homologous crossing-over in a heterozygote. The parental chromatids involved are distinguished by double and heavy lines. The regions coded for the α-polypeptides are indicated by dotted lines, and the letters locate the approximate regions corresponding to the chymotryptic peptides *N*, *F*, *S*, *C* and *J* referred to in the text

made, although we assume that the beginnings and/or ends of genes are specified in some way, and we recognize that the relative frequency but not the possibility of occurrence of some of the events to be discussed may be influenced by the presence and the amount of any DNA not coded for amino-acid sequences.

Partial gene duplications may or may not be completely functional so far as protein synthesis is concerned, depending on the particular point in the chromosome where the duplication begins, and on the nature of the base pair code specifying amino-acids and the ends of polypeptide chains. On theoretical grounds we would expect coding restrictions to limit the number of duplications of random length leading to the production of a polypeptide bridging the beginning of the duplication. For example, less than one in three random duplications would make 'sense' at the beginning of the duplicated region if each amino-acid is coded by one particular triplet of base pairs. On the other hand, if an amino-acid can be specified in more than one way the requirements for continuity of the corresponding polypeptide may be met more frequently at the beginning of the duplication, but may fail to be met at some other point (see Crick *et al.*[13] for further discussion of this problem). If integral numbers of amino-acid coding units are involved, the requirements for continuity may be met still more frequently and the whole of the duplication may make 'sense'. Although partly functional and non-functional duplications are thus conceivable, our experiments indicate that completely functional partial gene duplications occur.

Once it is realized that a new gene able to code for an uninterrupted sequence of amino-acids can be formed from pre-existing genes by chromosomal rearrangements, the possible importance of this process for the evolution of new proteins becomes apparent. Three of the many conceivable examples of such evolutionary events, related to duplications which could have been formed by non-homologous crossing-over, are indicated diagrammatically in Fig. 4.

A duplication, *I*, within the boundaries of a single gene, leads to a repeated sequence of amino-acids in the corresponding polypeptide (subject to the involvement of an integral number of amino-acid coding units). Unexpected properties can result from such repetitions, as, for example, the polymerization tendencies of the polypeptide hp 2α. Although the repeated sequence in hp 2α is extensive, there appears to be no *a priori* reason why shorter ones could not exist. The consequences of the involvement of non-integral numbers of amino-acid coding units in a partial gene duplication will, as indicated here, depend on the nature of the code. For example, the new gene might give rise only to that part of the (pre-existing) polypeptide sequence which is coded by the DNA preceding the duplicated region, or the pre-existing sequence may be followed, as a result of the shift in reading of the DNA code (cf. Crick *et al.*[13]), by a completely new polypeptide sequence extending over part or almost all of the duplication. Any partial gene duplications which are non-functional in polypeptide synthesis, or give rise to phenotypically inactive products, may behave like amorphic mutations. However, unlike amorphic mutations due to deletions, they will revert to the normal gene occasionally, as a result of unequal but homologous crossing-over within the locus in homozygotes (see following), or as a result of unequal but homologous sister strand or intrachromatid crossing-over in heterozygotes[14].

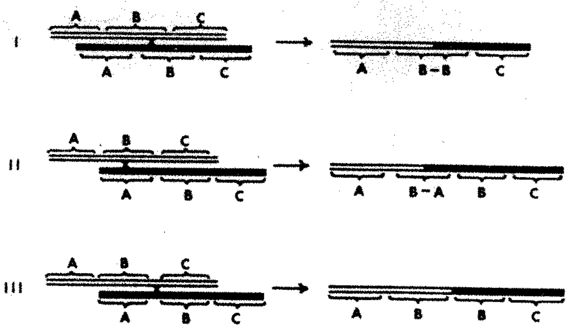

Fig. 4. Diagrammatic representation of the possible formation (by non-homologous crossing-over) and the consequences of duplications of several types. The brackets indicate DNA coded for polypeptide sequences. I, An intragenic duplication of the type suggested as involved in the evolution of Hp^2 from Hp^{1F} and Hp^{1S}; II, A duplication involving parts of two genes, leading to the formation of a new gene *B–A* without loss of the pre-existing genes *A* and *B*; III, a duplication of the same extent as II, but formed by crossing-over between genes. The result is a classical gene duplication, such as may have been involved in the evolution of the hæmoglobin polypeptide chains

A duplication involving parts of two genes, *II*, can lead to the formation of a new gene coded for a polypeptide sequence combining parts of the sequences of two pre-existing proteins if integral numbers of coding units are involved. Such a polypeptide might combine in one molecule properties formerly present in separate molecules. For example, in the case of enzymes it could have amino-acid sequences enabling it to combine with two substrate groups where its 'progenitors' could each combine with only one of them. (If non-integral numbers of coding units are involved the situation is similar to that discussed here.) Yet the evolution of such radically new proteins, by a single genetic event, need not be accompanied by loss of any genes for pre-existing proteins (Fig. 4). The alternate chromosome (not shown in the figure) formed during the non-homologous crossing-over leading to duplication *II* also has a new gene (*A–B*) which could code for a sequence of amino-acids with the portions corresponding to the genes *A* and *B* in the order A–B, in contrast to the order B–A for the duplication. This alternate chromosome, however, lacks the genes *A* and *B*, and so may have selective disadvantages.

Non-homologous crossing-over occurring between genes can lead to complete duplication of an existing gene (*III*).

Many types of chromosomal rearrangements, in addition to duplications, have been detected by genetic and cytological studies; for example, deletions, inversions, shifts, transpositions, etc. None of these would appear on *a priori* grounds to be confined to integral numbers of genes. We can therefore expect that protein variants will eventually be found corresponding to them, although until the base pair-amino-acid code is more completely known it is difficult to predict what proportion of these arrangements will fulfil the requirements for continuity in the corresponding polypeptides. The frequency of occurrence of cytologically detectable chromosomal rearrangements in naturally occurring populations of *Drosophila* and other species certainly indicates that re-arrangements are common evolutionary events.

Other proteins, in addition to the haptoglobins, have structures which suggest that chromosomal rearrangements were involved in their evolution. Thus, the porcine pituitary hormones α-melanotropin (αMSH) and adrenocorticotrophin (ACTH) both contain the same sequence of 13 amino-acids[15]. αMSH has an acyl group on the *N*-terminal amino-group and the terminal carboxyl-group is amidated. On the other hand, ACTH has a free *N*-terminal amino-group and 26 additional amino-acid residues on the *C*-terminal end. βMSH lacks the *N*- and *C*-terminal amino-acids of αMSH and has short, completely dissimilar sequences on both ends of the common sequence. Two amino-acid residues in the common sequence are interchanged in position. These structures are strongly suggestive of evolution involving chromosomal rearrangements at some stage. Many proteolytic enzymes (for example, trypsin and chymotrypsin) have portions of their sequences in common, but in general their structures differ greatly[16]. They could also have evolved by chromosomal rearrangements.

Consequences of unequal but homologous crossing-over at the Hp locus. Several consequences of the intragenic duplication probably involved in the gene Hp^2 can be predicted by considering other systems involving duplications. The 'Bar' allele in *Drosophila* is associated with a cytologically demonstrable duplication[17,18]. Homozygotes for 'Bar' are relatively frequently involved in unequal but homologous crossing-over[19], as a result of the displaced synapsis possible when there is a duplication in the genome. (Unequal but homologous crossing-over must be distinguished from non-homologous crossing-over, although both involve displaced synapsis. The latter, as indicated in Fig. 3, involves crossing-over between chromosomal regions which are not equivalent in their gene structure; it is consequently a rare event, and the subsequent action of the genes involved will be dependent on the requirements for continuity discussed here. Unequal but homologous crossing-over, on the other hand, involves crossing-over between chromosomal regions which are of equivalent structure but which are not in the same relative positions on the two chromosomes. Unequal but homologous crossing-over will not usually change the 'sense' of the DNA involved, and its frequency will be determined only by the frequency of displaced synapsis and by the map length of the corresponding duplicated or displaced chromosomal segment.) This unequal crossing-over in *Drosophila* gives rise to the formation of "double 'Bar' ", associated with a cytological triplication, or to reversion to 'wild-type' which lacks the original 'Bar' duplication. Homozygous individuals of the genotype Hp^2/Hp^2 are in many ways analogous to homozygotes for the 'Bar' allele. Unequal crossing-over would therefore be expected to occur occasionally in such individuals, either with the production of a triplicated haptoglobin gene (instead of the usual duplicated Hp^2 gene) or with reversion to one of the original 'wild-type' genes Hp^{1F} or Hp^{1S} (see Fig. 5 I). In the absence of information about the nature of the gene Hp^2 these events would be interpreted as mutations and the *Hp* locus would be described as having a high mutation rate.

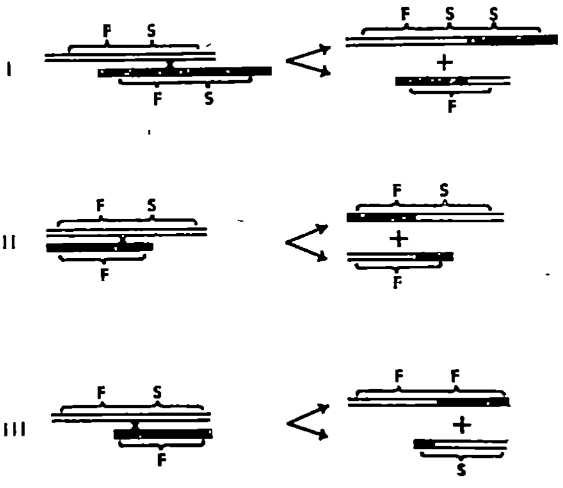

Fig. 5. Diagrammatic representation of the consequences of: I, unequal but homologous crossing-over occurring during displaced synapsis in a Hp^2/Hp^2 homozygote, leading to the possible evolution of a haptoglobin triplication or to reversion of Hp^2 to Hp^{1F} or Hp^{1S}; II and III, crossing-over within the locus in a heterozygous individual (Hp^2/Hp^{1F}) during the two possible synaptic configurations. This crossing-over will always be unequal and can lead to the production of four types of Hp^2 gene, and to the formation of a gamete containing the gene Hp^{1S} in an individual of genotype Hp^2/Hp^{1F}

A rare and unusual type of haptoglobin (the Johnson type), discovered by Dr. E. R. Giblett in a Negro woman and her daughter in Seattle, is associated with a rare gene, Hp^{2J}, in heterozygous combination with the common Hp^{1S} allele. Preliminary tests, involving comparison of the mobilities of the α-chains in starch gels at different starch concentrations[20], indicate that the corresponding polypeptide *hp* 2Jα, is considerably larger than *hp* 2α. This suggests that the gene Hp^{2J} could be the triplication formed by unequal but homologous crossing-over in a homozygote Hp^2/Hp^2 during displaced synapsis. This suggestion receives some confirmation from the recent discovery of the Johnson type in other widely separated racial groups (Dr. E. R. Giblett has found it in a Canadian Mennonite and two Hawaiian Chinese, Dr. K. Henningsen in a Dane, Dr. J. Hirschfeld in a Swede, Dr. R. L. Kirk in an Australian Dutch, Dr. J. Lundevall and Mrs. E. A. Fleischer in three Norwegians, Dr. B. Romat in a Kurdish Jew). It seems highly improbable that the gene Hp^{2J} in the Seattle Negroes and these other genes have a common ancestor; yet they appear to be identical as judged by the phenotypes. The cause of their identity could be a common mechanism of formation rather than descent from a common ancestor. If the gene Hp^{2J} does prove to be an intragenic triplication then the Johnson type (genotype Hp^{2J}/Hp^{1S}) provides an excellent example and a possible explanation at the molecular level of the stable position effect, since the Johnson phenotype is readily distinguished from *Hp* 2–2, in which the same genetic material is distributed equally between the two chromosomes.

Other unusual serum samples very similar to but not identical with the Johnson type have also been found and sent to us for testing. Unfortunately, all had been shipped considerable distances and were not freshly collected, so that the observed small differences are difficult to evaluate. However, differences would be expected in terms of the triplication hypothesis, since there should be eight different forms of a triplicated haptoglobin gene (see later) and consequently sixteen heterozygous combinations with the genes Hp^{1F} and Hp^{1S}.

Synapsis in heterozygotes Hp^2/Hp^{1F} and Hp^2/Hp^{1S} can occur in two ways (Fig. 5 II and III), as a result of the duplicate nature of the gene Hp^2. Crossing-over within the locus (which will always be unequal) should therefore lead eventually to the occurrence in the gene pool of all the four possible types of Hp^2. Thus, if we assume that the original Hp^2 gene was FS, then intragenic crossing-over in heterozygotes will lead to the formation of Hp^2 genes which are FF, SS, and SF. The relative chances of finding these types is difficult to predict, since we have insufficient knowledge about the frequency of the corresponding unequal crossing-over, and of the selective forces involved, to be able to estimate the equilibrium frequencies of the different genes. However, we may already have had some samples of hp 2α from individuals who are $Hp^{2(FF)}/Hp^{2(FF)}$ or $Hp^{2(FS)}/Hp^{2(FF)}$, as three out of fifteen single donor hp 2α preparations showed complete, or almost complete absence of the peptide S characteristic of hp 1Sα (Fig. 1), but clearly showed the corresponding F peptide. In any event, we predict that four types of Hp^2 gene are possible, and are undertaking a search for them.

In summary, we conclude that the haptoglobin system provides examples of the effect on the structure of a single polypeptide chain of both a 'point' mutation and chromosomal rearrangements. We suggest that proteins with radically changed properties can be formed as a consequence of the single genetic event of a chromosonal rearrangement involving non-integral numbers of genes. Chromosomal rearrangements of this type appear to provide a mechanism for achieving more rapid and extensive changes in protein structure during evolution than are possible by point mutations, even when preceded by gene duplication. New genes formed by chromosomal rearrangements need not be accompanied by loss to the organism of any pre-existing genes.

This work was supported in part by grants from the U.S. National Science Foundation, and the Medical Research Council, Canada. We thank Dr. W. E. Nance for his help during the preparation of the manuscript and acknowledge many helpful discussions of the work with him, Drs. J. F. Crow, N. E. Morton, and L. Sandler.

A THEORY OF S GENE STRUCTURE

By DR. K. K. PANDEY

Crop Research Division, Department of Scientific and Industrial Research, Lincoln, New Zealand

BECAUSE of technical limitations, comparatively few compound loci in higher plants are amenable to detailed analysis. Exceptional in this respect is the *S* gene controlling self-incompatibility. Some understanding of this complex gene at the phenotypic level has been derived from its behaviour in autopolyploids; in spontaneous and induced mutants; and in interspecific crosses. Thus different *S* alleles in diploid pollen may diversely show independent action, dominance, or competitive interaction[1,2]; the last, which is expressed after selfing, often results in self-compatibility. Spontaneous and irradiation-induced mutants involving the *S* alleles in *Oenothera organensis*[3], *Prunus avium*[4], *Trifolium pratense* and *T. repens*[5,6] have shown that the *S* gene consists of at least two independently mutable units, one governing the specificity of the pollen, the other that of the style; a change or loss of specificity in one or the other leads to self-compatibility. Brewbaker and Natrajan[7], however, found self-compatible plants in *Petunia inflata* which were not due to mutations of the *S* allele. These plants, which arose in the selfed generation following X-irradiation of the pollen mother cells, were found to carry a supernumerary *S*-bearing centric chromosome fragment, and self-compatibility was due to competitive interaction between the two different *S* alleles carried by pollen bearing the fragment. The *S* allele mutation hypothesis was therefore challenged, but its general validity was firmly re-established by Lewis[8].

Recent advances in the analysis of the *S* gene complex have been made through the examination of interspecific crosses. From a large number of crosses between several genera and families, Lewis and Crowe[9] and Crowe[10] showed that there were two kinds of self-compatible species: Sc species, which have an allele S_f that is similar to the experimentally induced pollen-part mutant; and SC species, which have a self-fertile allele not yet recovered in mutation studies. The two groups of species are distinguished by their interactions in crosses with self-incompatible (SI) species, thus:

SI × Sc—Compatible; Sc × SI—Compatible
SI × SC—Incompatible; SC × SI—Compatible

SI styles accept Sc pollen but reject SC pollen.

To explain this, Lewis and Crowe suggested a modified form of Straub's[11] hypothesis, that specificity molecules are attached to a growth substance and that a mutant allele which has lost its pollen specificity unit produces a 'bare' pollen growth substance. Such unprotected pollen growth substance is inactivated by a specific incompatibility substance in the style. The problem arose that if both Sc and SC species had lost their pollen specificity why was only the SC pollen rejected by SI styles. Experimental evidence with induced mutants, taken in conjunction with published evidence on self-fertility in certain species suggests[9] that Sc species had become self-compatible comparatively recently, whereas in SC species self-compatibility was long established. This observation, while explaining the evolutionary status of the two groups of species, does not account for the sharp differences in the behaviour of their two kinds of *S* alleles. A clue to the solution of this problem is provided by studies in *Nicotiana*.

N. alata (SI) and *N. langsdorffii* (Sc), as expected, are usually reciprocally compatible. However, Anderson and de Winton[12] found one strain of *N. alata* which rejected the pollen of *N. langsdorffii*. This behaviour was controlled by a self-incompatible *S* allele, named S_F, which when present in the style of *N. alata* rejected the pollen of *N. langsdorffii*. That this allele is not so rare as at first thought has been shown by me (unpublished results): 15 out of 34 plants of *N. alata* from three different seed sources were heterozygous for this allele.

The S_F allele in *N. alata* produces a certain specificity in the style which matches not only that of its own pollen but also that produced by the S_f allele in *N. langsdorffii*. It is obvious that a pollen specificity, as between S_F and S_f, that is common to two species, must be of a primary nature. It has been assumed[6,9] that S_f has lost its pollen specificity making *N. langsdorffii* self-fertile. The fact, however, that pollen carrying this allele is rejected by *N. alata* styles carrying S_F shows that a certain specificity remains in the S_f, an allele which occurs in species that have recently become self-fertile. This would suggest that the primary specificity still remains after the secondary (common) specificity has been lost, and that the primary specificity is physiologically interposed between the growth substance and the secondary specificity.

An allele which has lost secondary specificity in both pollen and style would still express primary specificity in both organs and would be self-incompatible. The S_F allele may be such an allele. Another allele which has lost secondary specificity in the pollen only would still express primary specificity in the pollen and secondary specificity in the style and would therefore be self-compatible The allele S_f of Sc species may be such an allele. Pollen with the S_f allele would be rejected by a style containing the S_F allele because the primary specificity is expressed in both pollen and style.

On the above hypothesis, the SC species, in which self-compatibility was long-established, would have an allele, here called S_C, which has lost both the primary and the secondary specificity in the pollen and thus produces an unprotected pollen growth substance. Pollen with such an allele is, therefore, rejected on an SI style. Evidence suggesting the existence of a growth substance in the style has been found by me (unpublished results) in two Mexican *Solanum* species, *S. pinnatisectum* and *S. ehrenbergii*. Styles of certain strains of these species, supposedly homozygous for an allele, named S_{IC}, reject all SI pollen. This situation in the style corresponds to that presented by the S_C allele in the pollen; in the former the style is incompatible with all SI pollen, in the latter the SC pollen is incompatible with all SI styles. These reactions suggest that the S_{IC} allele is probably a stylar counterpart of the S_C allele, and produces an unprotected stylar growth substance which is inactivated by a specific substance in SI pollen.

An investigation of cross-compatibility relationships in 9 *Nicotiana* species by me (unpublished results) has shown that, of the self-compatible species, *N. glauca*, *N. longiflora*, *N. rustica*, *N. paniculata*, *N. sylvestris*, *N. glutinosa* and *N. tabacum* belong to the SC group and only *N. langsdorffii* to the Sc group; *N. alata* is an SI species.

Since it has been assumed that the SC species have an unprotected pollen growth substance, in order that these species be self-compatible their styles should lack specificity, either secondary or primary. But if the absence of these specificities alone left the stylar growth substance unprotected, they should be incompatible as females with Sc and SI pollen. However, this is not so; the styles of SC species are compatible with Sc and SI pollen, suggesting that their growth substance is still protected even when both specificities are lost. This would indicate that, contrary to the previous assumption, specific substances are not responsible for the protection of the growth substance; and leads to the assumption of a separate 'protective substance'. This component would be attached to the growth substance and would prevent its inactivation after both specificities are lost. The S_C allele, therefore, appears to have lost both specificities for pollen and for style, but has lost the protective substance only for pollen.

The apparent widespread occurrence of the S_C allele in flowering plants[9] suggests that this state of the *S* gene represents the minimum requirement of a dynamic species; for if the protective substance was lost in both pollen and style the species having such an allele would be completely incapable of exchanging genes with other species having any specificity and would thus be greatly restricted in its evolutionary development.

It is therefore tentatively suggested that the physiology of the *S* gene is controlled by 4 components: growth substance, protective substance, primary specificity and secondary specificity, each with corresponding pollen and stylar units attached in that order, the component for secondary specificity being added last. There appear to be two possibilities of mutations of *S* alleles: (1) those that could give rise to variants of the common S_I alleles through recombination, presumably on Fisher's model[13] and (2) those that give rise to new forms of *S* alleles, through loss mutations. The second group may involve the loss of one or more of the 3 components, protective substance, primary specificity and secondary specificity. The fourth component, growth substance, may or may not be a part of the *S* gene complex, since it is basic to all functional pollen. Considering that viable mutations of these units, occurring singly or in multiples, take place only sequentially starting from the secondary specificity, 16 kinds of *S* alleles are possible. Six of these alleles have been either directly identified through the study of spontaneous and induced mutants of *S* alleles or deduced from the results of interspecific hybridization; these are listed in Table 1 and shown diagrammatically in Fig. 1.

Generally, the available data on intra- and interspecific crosses can be explained satisfactorily on the basis of the above theory of the *S* gene structure. The reported exceptions usually involve wide intergeneric crosses[9] and rarely interspecific crosses[14]. They are mostly in the SI × SI combinations which, contrary to expectations, are incompatible. It is likely that in certain wide crosses factors other than

Table 1. Hypothetical Structure of Different *S* Alleles

Type of allele	Pollen / Style: Growth substance	Pollen / Style: Protective substance	Pollen / Style: Primary specificity	Pollen / Style: Secondary specificity	Species (References in the text)
S_I (normal)	$\frac{+}{+}$	$\frac{+}{+}$	$\frac{+}{+}$	$\frac{+}{+}$	All normal homomorphic self-incompatible species.
S_f	$\frac{+}{+}$	$\frac{+}{+}$	$\frac{+}{+}$	$\frac{-}{+}$	Mutants in *Oenothera organensis*, *Trifolium pratense*, *T. repens*, *Prunus avium* and many wild self-compatible species.
S_{fc}	$\frac{+}{+}$	$\frac{+}{+}$	$\frac{+}{+}$	$\frac{+}{-}$	Mutants in *Trifolium pratense* and *Prunus avium*.
S_F	$\frac{+}{+}$	$\frac{+}{+}$	$\frac{+}{+}$	$\frac{-}{-}$	Certain strains of *Nicotiana alata*.
S_{Ic}	$\frac{+}{+}$	$\frac{+}{-}$	$\frac{+}{-}$	$\frac{+}{-}$	Certain strains of *Solanum pinnatisectum* and *S. ehrenbergii*.
S_C	$\frac{+}{+}$	$\frac{-}{+}$	$\frac{-}{-}$	$\frac{-}{-}$	Many wild self-compatible species.

S-gene incompatibility, such as gross physico-chemical differences in the nature of styles, may be responsible for pollen-style inhibition. However, it is possible that, in association with enzymes which help in the pollen-tube penetration of the stigmatic cuticle[15,16], there is a general enzyme operating in distant crosses which inactivates all secondary specificity, thus allowing the expression of the primary specificity in both pollen and style and therefore causing incompatibility.

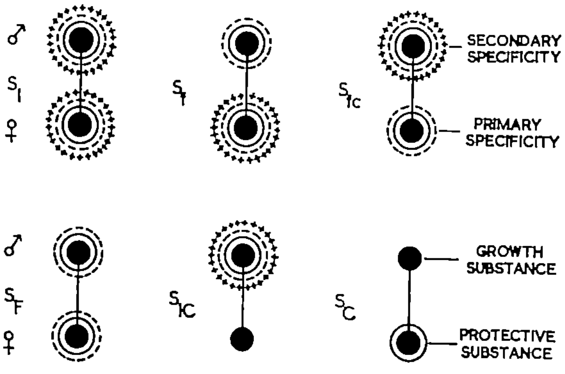

Fig. 1. Diagrammatic representation of the 6 kinds of *S* alleles described in Table 1

A detailed investigation of *S* alleles in intra- and inter-specific hybrids, and the attempt to produce them artificially, should help to elucidate the fine structure of the *S* gene.

DEVELOPMENT OF THE THYMUS IN THE HUMAN FŒTUS AND ITS RELATION TO IMMUNOLOGICAL POTENTIAL

By H. E. M. KAY, J. H. L. PLAYFAIR, M. WOLFENDALE and P. K. HOPPER

Royal Marsden Hospital, Fulham Road, London, S.W.3

RECENT work by Auerbach[1], Miller[2], and Kalmutz[3] has emphasized the importance of the thymus in the development of the lymphoid system and the dependent property of immunity. The possibility of exploiting fœtal tolerance to achieve tissue transplants in man may be limited by the duration of the initial period of immune inactivity.

Elsewhere[4] we have described the emergence of the small lymphocyte of the peripheral blood in man and contrasted the timing of this event with the rodents, rats and mice. A similar, and perhaps more significant, contrast is to be found in the growth of the thymus.

Thymic weights of 289 young and mid-term human fœtuses are recorded in Fig. 1. These are supplemented by figures from the few relevant publications[5-7] which are mostly concerned with older fœtuses. At first sight the rate of growth throughout fœtal life appears to be fairly regular, but when expressed in relation to the body-weight (Fig. 2) it is seen to level off at the beginning of the third trimester. A gradual decline follows which is already perceptible at birth and continues thereafter. The initial upgradient from 12 to 24 weeks can be deduced fairly accurately from the data we have collected. The later points, however, which define the acme of the curve and the shape of the decline are less certain. First, some of the figures on which they are based were published as mean thymic weights in groups of fœtuses within a particular weight range and with a mean crown-rump length, not an entirely satisfactory mode of presentation. Secondly, an opportunity for error arises from the possible delay in older fœtuses between delivery and death, during which time the thymus may partly involute as a result of stress; and a further objection is that stillbirths of premature infants and deaths within 24 h of delivery may be due to some disease which itself affects the thymus. Erythroblastosis fœtalis is an example[6], but such diseases form only a minority of the cases and will not unduly affect the mean values. Nor is the effect of delay likely to be serious, although there may be some adventitious flattening of the top of the curve.

Fig. 3 presents similar data relating to splenic weight. The curve here is somewhat different. The development of the spleen lags behind that of the thymus and the increase in relative weight continues up to the time of birth[5,6,8]. The spleen is, of course, a composite organ, more versatile in hæmopoiesis than the thymus, more prone also to engorgement with blood. The latter factor may partly account for the apparent discrepancy of observed values where our data overlap others and for the difference between the mean weights at birth as given by Potter[6] and by Coppoletta and Wolbach[8].

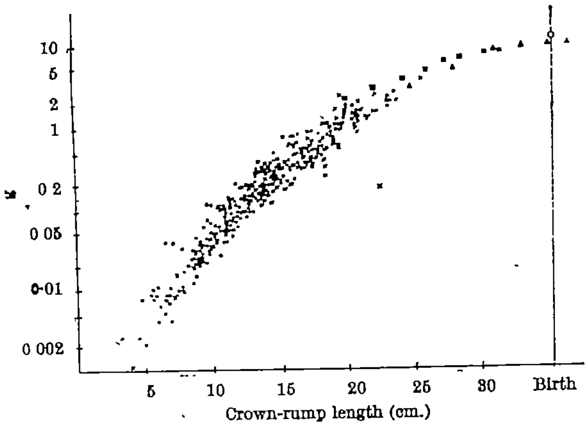

Fig. 1. Weight of fœtal thymuses in relation to crown-rump length. ●, Hysterotomy cases; ×, spontaneous abortions; ■, Silverman (ref. 5); △, Potter (ref. 6); ○, Russkoff (ref. 7)

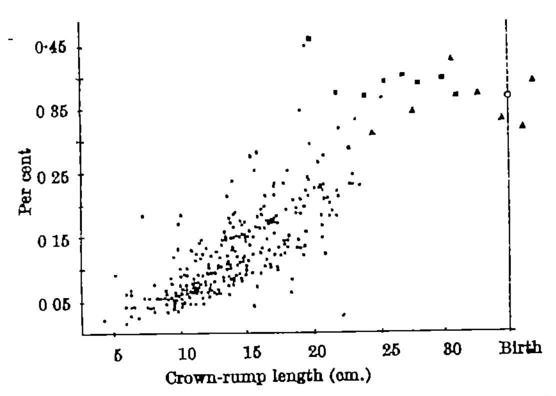

Fig. 2. Weight of fœtal thymuses as a proportion of body-weight. ●, Hysterotomies and spontaneous abortions; ■, Silverman (ref. 5), △, Potter (ref. 6), ○, Russkoff (ref. 7)

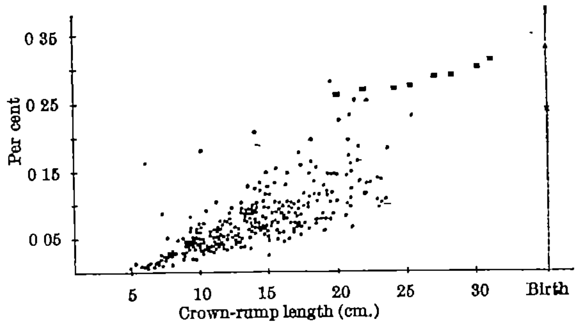

Fig. 3. Weight of fœtal spleens as a percentage of body-weight. ●, Hysterotomies and spontaneous abortions, ■, Silverman (ref. 5); △, Potter (ref. 6); ×, Coppoletta and Wolbach (ref. 8)

The three events in lymphoid development which are susceptible to quantitative analysis[5–10] are shown in Fig. 4. No firm conclusions should be drawn from the relationships; but the evidence is compatible with the hypothesis that cells from the thymus colonize the other lymphoid tissues of the body. It is also tempting to surmise that while the circulating lymphocytes of the fœtus are derived from the thymus post-natal lymphocytes may originate elsewhere also.

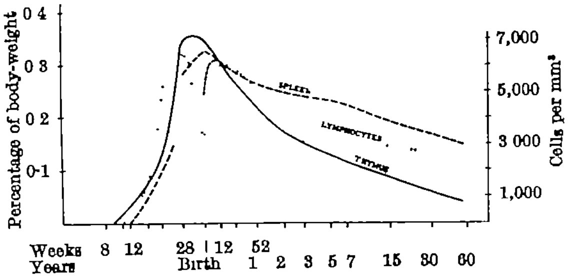

Fig. 4. Development of lymphoid system. Data from refs. 4–10

In Fig. 5 the development of the thymus has been compared in three species[10–13]. In the mouse the period of life in which tolerance to foreign antigens can be easily induced ceases within the first ten days of post-natal life[14], corresponding to the phase of most rapid thymus growth[13] and the attainment of its peak ratio. In the sheep, by contrast, immunological potential has been demonstrated in the second half of gestation[15,16], and the development of the thymus seems to be correspondingly advanced. If, as is possible, the two events are causally connected the phase of immune passivity in man may be restricted to early fœtal life. Silverstein[17] has deduced, from histological evidence in congenital syphilis, that six months may be the limit, but any such figure must almost certainly be qualified in the context of other antigens and variations in antigen-dosage. To this early capacity for immune reaction

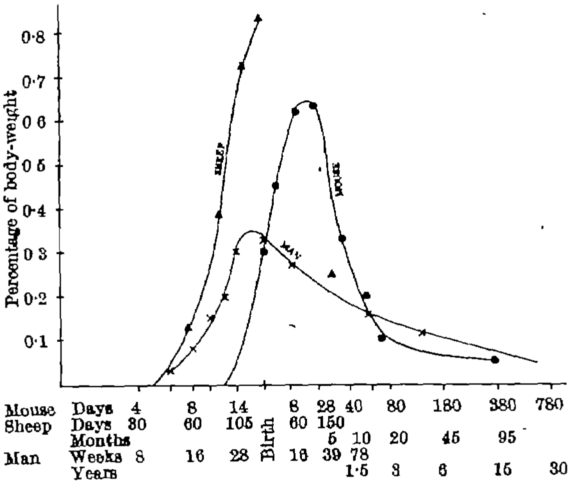

Fig. 5. Comparison of thymic developments in man (from Fig. 2 and ref. 10), mouse (refs. 1, 13) and sheep (refs. 11, 12 and our own unpublished data)

may be attributed the failure so far to achieve hæmopoietic transplants in the human fœtus, though the occurrence of natural blood-group chimæras in man in evidence that such transplants are theoretically possible.

We thank Dr. J. F. A. P. Miller for permission to use his data and for helpful criticism. This work was supported by a grant from the Medical Research Council.

EFFECT OF BONE-MARROW ON REGENERATION OF LIVER OF X-IRRADIATED RATS

By E. CZEIZEL, G. VACZÓ and DR. P. KERTAI
State Institute of Public Health, Budapest

ONE of the most important problems in experiments carried out in radiation biology is to find out how the ionizing radiation exercises its effects on the inhibition of cell-division. Regenerating liver seems to be a very good subject for experiments because, while dividing cells are very rare in intact liver, numerous cell-divisions can be noticed in liver which is regenerating. In the case of rat liver the intensity of cell-division can be easily followed by simple weighing, and this facilitates the examination.

The effect of X-irradiation on regenerating liver has been examined by several authors, however with conflicting results[1–15]. On the basis of the examinations it can be certainly stated that while normal liver is relatively resistant to irradiation, and regenerating hepatic tissue exposed to local irradiation behaves similarly (when irradiating the whole body), the degree of regeneration, the intake of phosphorus-32 by the liver under regeneration and its DNA synthesis decrease.

As is well known from the works of Jacobson[16,17] and Lorenz[18], protection of the spleen and bone-marrow, that is, injection of spleen and medulla suspension, diminishes the lethal effect of X-rays and has an effect on the regeneration of the bone-marrow. With regard to the effect of the bone-marrow on liver, Kretchmar and Congdon[19] noted an increase in the weight of the whole liver in mice exposed to X-irradiation and treated with bone-marrow suspensions. In the course of our present experiments we wished to clarify the effect of bone-marrow extracts on liver regeneration of normal and X-rayed rats.

Partial hepatectomy was carried out according to the method of Higgins and Anderson[20] on 173 male and female albino rats (130–320 g body-weight) bred at this Institute.

In 51 animals used for producing bone-marrow extracts, the weight of the liver lobules removed by partial hepatectomy and that of the remaining portions was measured, and we found that the part removed through partial hepatectomy represented 63·2 per cent of the whole liver, hence the residuum was 36·8 per cent. The percentage degree of regeneration has been established on the basis of Canzanelli's formula:

$$\frac{\text{Weight of the whole liver under regeneration} - \text{Weight of the residuum}}{\text{Weight of the two liver lobules removed by operation}} \times 100$$

while the hepatic tissues formed within one week were calculated in 100 g of body-weight.

Whole-body X-irradiation was effected 24 h after the operation. In each case a dose measured in 500 r. air was applied from a distance of 40 cm, with a 180 kV, 15 m.amp, 0·5-mm copper filter, where the air doses in r./m was 67·6.

In order to protect the region of the liver a lead plate covering the body from the xyphoid process to the upper contour of the pelvis was placed on the abdomen of the animal fixed on the operating table. Partial protection of the bone-marrow was effected by exposing only the region between the lower part of the sternum and the upper edge of the pelvis. We use the term 'partial protection of the bone-marrow' because we were unable to protect either

Table 1. EFFECT OF LIVER AND BONE-MARROW SHIELDING, AS WELL AS EFFECT OF NORMAL AND X-RAY-TREATED BONE-MARROW ON LIVER-REGENERATION OF WHOLE-BODY IRRADIATED ANIMALS

No. of exps.	Group	Mortality (per cent)	No. of animals	r./100 g	Per cent	Note	
1	Partially hepatectomy	10	27	2·27 ± 0·08	89·7	—	
2	Partially hepatectomy + X-ray	32	17	1·48 ± 0·05	59·6	$t_{42} = 13{\cdot}898$	$P \ll 0{\cdot}01$
3	Partially hepatectomy + X-ray + liver shielding	21	25	1·68 ± 0·05	68·7	$t_{40} = 2{\cdot}270$	$P < 0{\cdot}05$
4	Partially hepatectomy + X-ray + liver shielding + partially bone-marrow shielding	13	26	1·78 ± 0·06	77·7	$t_{41} = 4{\cdot}400$	$P < 0{\cdot}01$
5	Partially hepatectomy + X-ray + bone-marrow administration	12	14	2·13 ± 0·05	88·6	$t_{29} = 8{\cdot}170$	$P \ll 0{\cdot}01$
6	Partially hepatectomy + X-ray + irradiated bone-marrow administration	27	8	1·45 ± 0·09	57·2	$t_{23} = 0{\cdot}303$	$P > 0{\cdot}5$
